PHILADELPHIA: COLLINS, PRINTER, 705 JAYNE STREET.

ADVERTISEMENT.

This volume forms the twentieth of a series, composed of original memoirs on different branches of knowledge, published at the expense, and under the direction, of the Smithsonian Institution. The publication of this series forms part of a general plan adopted for carrying into effect the benevolent intentions of James Smithson, Esq., of England. This gentleman left his property in trust to the United States of America, to found, at Washington, an institution which should bear his own name, and have for its objects the "increase and diffusion of knowledge among This trust was accepted by the Government of the United States, and an Act of Congress was passed August 10, 1846, constituting the President and the other principal executive officers of the general government, the Chief Justice of the Supreme Court, the Mayor of Washington, and such other persons as they might elect honorary members, an establishment under the name of the "Smithsonian INSTITUTION FOR THE INCREASE AND DIFFUSION OF KNOWLEDGE AMONG MEN." The members and honorary members of this establishment are to hold stated and special meetings for the supervision of the affairs of the Institution, and for the advice and instruction of a Board of Regents, to whom the financial and other affairs are intrusted.

The Board of Regents consists of two members ex officio of the establishment, namely, the Vice-President of the United States and the Chief Justice of the Supreme Court, together with twelve other members, three of whom are appointed by the Senate from its own body, three by the House of Representatives from its members, and six persons appointed by a joint resolution of both houses. To this Board is given the power of electing a Secretary and other officers, for conducting the active operations of the Institution.

To carry into effect the purposes of the testator, the plan of organization should evidently embrace two objects: one, the increase of knowledge by the addition of new truths to the existing stock; the other, the diffusion of knowledge, thus increased, among men. No restriction is made in favor of any kind of knowledge; and, hence, each branch is entitled to, and should receive, a share of attention.

¹ This office has been abolished.

The Act of Congress, establishing the Institution, directs, as a part of the plan of organization, the formation of a Library, a Museum, and a Gallery of Art, together with provisions for physical research and popular lectures, while it leaves to the Regents the power of adopting such other parts of an organization as they may deem best suited to promote the objects of the bequest.

After much deliberation, the Regents resolved to divide the annual income into two parts—one part to be devoted to the increase and diffusion of knowledge by means of original research and publications—the other part of the income to be applied in accordance with the requirements of the Act of Congress, to the gradual formation of a Library, a Museum, and a Gallery of Art.

The following are the details of the parts of the general plan of organization provisionally adopted at the meeting of the Regents, Dec. 8, 1847.

DETAILS OF THE FIRST PART OF THE PLAN.

- I. To increase Knowledge.—It is proposed to stimulate research, by offering rewards for original memoirs on all subjects of investigation.
- 1. The memoirs thus obtained, to be published in a series of volumes, in a quarto form, and entitled "Smithsonian Contributions to Knowledge."
- 2. No memoir, on subjects of physical science, to be accepted for publication, which does not furnish a positive addition to human knowledge, resting on original research; and all unverified speculations to be rejected.
- 3. Each memoir presented to the Institution, to be submitted for examination to a commission of persons of reputation for learning in the branch to which the memoir pertains; and to be accepted for publication only in case the report of this commission is favorable.
- 4. The commission to be chosen by the officers of the Institution, and the name of the author, as far as practicable, concealed, unless a favorable decision be made.
- 5. The volumes of the memoirs to be exchanged for the Transactions of literary and scientific societies, and copies to be given to all the colleges, and principal libraries, in this country. One part of the remaining copies may be offered for sale; and the other carefully preserved, to form complete sets of the work, to supply the demand from new institutions.
- 6. An abstract, or popular account, of the contents of these memoirs to be given to the public, through the annual report of the Regents to Congress.

- II. To increase Knowledge.—It is also proposed to appropriate a portion of the income, annually, to special objects of research, under the direction of suitable persons.
- 1. The objects, and the amount appropriated, to be recommended by counsellors of the Institution.
- 2. Appropriations in different years to different objects; so that, in course of time, each branch of knowledge may receive a share.
- 3. The results obtained from these appropriations to be published, with the memoirs before mentioned, in the volumes of the Smithsonian Contributions to Knowledge.
 - 4. Examples of objects for which appropriations may be made:-
- (1.) System of extended meteorological observations for solving the problem of American storms.
- (2.) Explorations in descriptive natural history, and geological, mathematical, and topographical surveys, to collect material for the formation of a Physical Atlas of the United States.
- (3.) Solution of experimental problems, such as a new determination of the weight of the earth, of the velocity of electricity, and of light; chemical analyses of soils and plants; collection and publication of articles of science, accumulated in the offices of Government.
- (4.) Institution of statistical inquiries with reference to physical, moral, and political subjects.
- (5.) Historical researches, and accurate surveys of places celebrated in American history.
- (6.) Ethnological researches, particularly with reference to the different races of men in North America; also explorations, and accurate surveys, of the mounds and other remains of the ancient people of our country.
- I. To diffuse Knowledge.—It is proposed to publish a series of reports, giving an account of the new discoveries in science, and of the changes made from year to year in all branches of knowledge not strictly professional.
- 1. Some of these reports may be published annually, others at longer intervals, as the income of the Institution or the changes in the branches of knowledge may indicate.
- 2. The reports are to be prepared by collaborators, eminent in the different branches of knowledge.

- 3. Each collaborator to be furnished with the journals and publications, domestic and foreign, necessary to the compilation of his report; to be paid a certain sum for his labors, and to be named on the title-page of the report.
- 4. The reports to be published in separate parts, so that persons interested in a particular branch, can procure the parts relating to it, without purchasing the whole.
- 5. These reports may be presented to Congress, for partial distribution, the remaining copies to be given to literary and scientific institutions, and sold to individuals for a moderate price.

The following are some of the subjects which may be embraced in the reports:—

I. PHYSICAL CLASS.

- 1. Physics, including astronomy, natural philosophy, chemistry, and meteorology.
- 2. Natural history, including botany, zoology, geology, &c
- 3. Agriculture.
- 4. Application of science to arts.

II. MORAL AND POLITICAL CLASS.

- 5. Ethnology, including particular history, comparative philology, antiquities, &c.
- 6. Statistics and political economy.
- 7. Mental and moral philosophy.
- 8. A survey of the political events of the world; penal reform, &c.

III. LITERATURE AND THE FINE ARTS.

- 9. Modern literature.
- 10. The fine arts, and their application to the useful arts.
- 11. Bibliography. •
- 12. Obituary notices of distinguished individuals.

II. To diffuse Knowledge.—It is proposed to publish occasionally separate treatises on subjects of general interest.

- 1. These treatises may occasionally consist of valuable memoirs translated from foreign languages, or of articles prepared under the direction of the Institution, or procured by offering premiums for the best exposition of a given subject.
- 2. The treatises to be submitted to a commission of competent judges, previous to their publication.

DETAILS OF THE SECOND PART OF THE PLAN OF ORGANIZATION.

This part contemplates the formation of a Library, a Museum, and a Gallery of Art.

- 1. To carry out the plan before described, a library will be required, consisting, 1st, of a complete collection of the transactions and proceedings of all the learned societies of the world; 2d, of the more important current periodical publications, and other works necessary in preparing the periodical reports.
- 2. The Institution should make special collections, particularly of objects to verify its own publications. Also a collection of instruments of research in all branches of experimental science.
- 3. With reference to the collection of books, other than those mentioned above, catalogues of all the different libraries in the United States should be procured, in order that the valuable books first purchased may be such as are not to be found elsewhere in the United States.
- 4. Also catalogues of memoirs, and of books in foreign libraries, and other materials, should be collected, for rendering the Institution a centre of bibliographical knowledge, whence the student may be directed to any work which he may require.
- 5. It is believed that the collections in natural history will increase by donation, as rapidly as the income of the Institution can make provision for their reception; and, therefore, it will seldom be necessary to purchase any article of this kind.
- 6. Attempts should be made to procure for the gallery of art, casts of the most celebrated articles of ancient and modern sculpture.
- 7. The arts may be encouraged by providing a room, free of expense, for the exhibition of the objects of the Art-Union, and other similar societies.
- 8. A small appropriation should annually be made for models of antiquity, such as those of the remains of ancient temples, &c.
- 9. The Secretary and his assistants, during the session of Congress, will be required to illustrate new discoveries in science, and to exhibit new objects of art; distinguished individuals should also be invited to give lectures on subjects of general interest.

In accordance with the rules adopted in the programme of organization, each memoir in this volume has been favorably reported on by a Commission appointed

for its examination. It is however impossible, in most cases, to verify the statements of an author; and, therefore, neither the Commission nor the Institution can be responsible for more than the general character of a memoir.

The following rules have been adopted for the distribution of the quarto volumes of the Smithsonian Contributions:—

- 1. They are to be presented to all learned societies which publish Transactions, and give copies of these, in exchange, to the Institution.
- 2. Also, to all foreign libraries of the first class, provided they give in exchange their catalogues or other publications, or an equivalent from their duplicate volumes.
- 3. To all the colleges in actual operation in this country, provided they furnish, in return, meteorological observations, catalogues of their libraries and of their students, and all other publications issued by them relative to their organization and history.
- 4. To all States and Territories, provided there be given, in return, copies of all documents published under their authority.
- 5. To all incorporated public libraries in this country, not included in any of the foregoing classes, now containing more than 10,000 volumes; and to smaller libraries, where a whole State or large district would be otherwise unsupplied.

- Plate 13. Mean Annual Direction of the Wind in the United States: showing the Resultants obtained by taking the Velocity into account, as compared with those derived from Time only.
- Plate 14. Maps of Isobars or Lines of Equal Atmospheric Pressure at Sea-level, for the Year, January and July.
- Plate 15. Relative Prevalence of Winds from the Different Points of the Compass, in Summer and Winter, in the Arctic Regions.
- Plate 16. Relative Prevalence of Winds from the Different Points of the Compass, in Summer and Winter, in Europe, south of Latitude 60°.
- Plate 17. Relative Prevalence of Winds from the Different Points of the Compass, in Summer and Winter, in Asia and Africa, between 25° and 60° North Latitude.
- Plate 18. Relative Prevalence of Winds from the Different Points of the Compass, in Summer and Winter, in the Tropical Regions, North of the Equator.
- Plate 19. Relative Prevalence of Winds from the Different Points of the Compass, in Summer and Winter, in the Tropical Regions, South of the Equator.
- Plate 20. Relative Prevalence of Winds from the Different Points of the Compass, in Summer and Winter, in the Southern Temperate Zone, between Latitude 25° and 60° South.

- Plate 21. Relative Prevalence of Winds from the Different Points of the Compass, in Summer and Winter, in the Four Seasons.
- Plate 22. Relative Prevalence of Winds from the Different Points of the Compass, in Summer and Winter, in the United States.
- Plate 23. Barometrical Wind-Roses. Mean Annual Direction of the Wind contrasted with the Direction of the Wind that accompanies Maximum or Minimum Pressure.
- Plate 24. A Suggestive Chart, showing the Relation of the Winds to other Meteorological Elements.
- Plate 25. Chart illustrating the effect of Velocity in modifying the Annual Direction of the Wind.
- Plate 26. Deflecting Forces, showing the effect of Annual, Monthly and Diurnal Variation.

PREFACE.

This work has been prepared by the joint agency of the late Professor Coffin and the Smithsonian Institution, the former furnishing the general plan and oversight of the work, and such parts of the labor as could not be satisfactorily confided to others; while the latter contributed the greater part of the material, and defrayed the entire cost of making all the reductions and numerical computations, except what was done by Professor Coffin, or was found in other works. The resultants at the academies in the State of New York, computed by Dr. Franklin B. Hough, and those at numerous places in Russia, computed by Mr. Wesselowski, and some few others, have been made use of.

This work may be considered an extension of Professor Coffin's former one on the "Winds of the Northern Hemisphere," so as to embrace the entire surface of the globe so far as it has been accessible to scientific observation.

In the words of Professor Coffin, "the design is to show primarily-

"1st. The mean direction in which the lower currents of the atmosphere move over all parts of the surface of the earth, including in the term 'lower currents' all that part of the atmosphere on which direct observations can be made, whether by means of a vane or by the motions of the clouds.

"2d. The ratio that the progressive motion bears to the total distance travelled.
"3d. The modifications that the mean current undergoes in the different seasons' of the year.

"4th. The directions in which the forces act that produce these modifications.

"5th. The amount of their intensities, reckoned on the same scale as that which determines the mean annual direction.

"6th. To show, by separate solutions for the surface winds and those indicated by the motion of the clouds, how the two differ, and how they differ according as we do, or do not take into account the difference in the velocity of the different winds; the discussion of this latter question being confined chiefly to the observations reported to the Smithsonian Institution from the year 1854 to 1857 inclusive.

"The data used for elucidating these points consist of series of observations on

¹ To avoid confusion the months of December, January and February are designated as winter in the southern as well as the northern hemisphere, March, April, May as spring, etc.

² Monsoon influences.

winds made at 3223 different stations on land, and during numerous voyages at sea, extending from the parallel of 83° 16′ north latitude, to beyond the parallel of 75° south latitude (the extreme points ever reached by man) altogether embracing an aggregate period of over 18,500 years.

"The stations on land are distributed over its surface as follows:-

			Nu	mber	of stations.	Aggregate number of years.		
America						2077	over 12,380	
Europe						740	" 4,130	
•						244	496	
Africa						76	131	
Islands o	f the	seai				86	314	

"Of these stations in America, about 1900 are within the limits of the United States, viz., over 1400 which reported to the Smithsonian Institution between the beginning of the year 1854 and the end of 1869, over 300 military posts that reported to the Surgeon-General of the United States Army, and some 100 to 150 other places. The observations at the military posts embrace all that were reported from the commencement of the system in the year 1822 up to the end of 1859, together with those at posts west of the Mississippi for the succeeding ten years also, or up to the end of 1869.

"At sea, between the parallels of latitude 60° north and 60° south, the observations are mostly taken from the Wind and Current Charts prepared at the United States Naval Observatory, under the direction of Capt. M. F. Maury, which cover the entire Atlantic, Indian and South Pacific Oceans, and all of the North Pacific except a comparatively small portion, the completion of which is much to be desired, lying between the meridians of 150° east and 165° west from Greenwich; and nearly every square of 5° in latitude by 5° in longitude is more or less fully represented. For the Arctic and Antarctic Oceans, and the Mediterranean, Black and Red Seas, the material is derived mostly from other sources. The observations on the ocean embrace a total of a little more than one thousand years.

"The whole material is arranged in the form of tabular series, which require no explanation beyond what is given in the headings of the several columns; and for more ready reference to the data from any particular place, or group of places, as contained in the tables, as well as with a view to a more scientific arrangement of the whole, and for convenience in the discussion, the entire surface of the earth is conceived to be divided into 36 zones by parallels of latitude drawn 5° asunder, commencing at the north pole, and proceeding southerly; and in each zone the places of observation are arranged in the order of their longitudes, commencing at the 180th meridian from Greenwich, and proceeding easterly.

"The method of reduction is the same throughout as in my former work. Instead of giving the prevailing direction, or that point or points of the compass from which the winds blow most frequently, and rejecting all the rest, the traverse of the whole is resolved, in the same manner as that of a ship at sea. The former method, which was once almost the universal one, and which still finds advocates, may be useful

¹ Including Australia and Greenland.

in pointing out local peculiarities in the winds at different places, as affected by the geographical features of the surrounding country, but can give us no enlarged ideas of the movement of the air as a whole.¹ Suppose a particle of air to start from the point A, in the following diagram, and to move with a uniform velocity for 30 days as follows:—

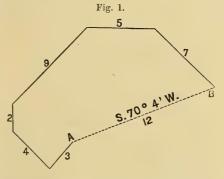

From the northeast for an aggregate period of 3 days

66	southeast	.66	66	4.6	4	66	
66	south	. 66	66	66	"2	66	
44	southwest	66	66	66	· 9	46	
66	west	66	. 66	66	" 5	166	
66	northwest	66	44	66	" 7	66	

the diagram represents its motions, and at the end of the 30 days the particle is

found at B. The bearing of the point A from it is now S. 70° 4′ W., its distance in a direct line equivalent to 12 days' travel, and the ratio of this distance to the whole distance travelled 40 per cent.

"Or, to express the same by formulæ after the method of Lambert, or of Mr. Charles A. Schott, of the United States Coast Survey,² or others, who have improved upon Lambert's method, let *n* represent the total number of observations (corresponding to the

sum of the sides of the foregoing polygon, except A B); θ , θ_1 , θ_2 , θ_3 the angles which the observed directions of the wind make with the meridian, reckoned round the compass from the north point eastward through 360° ; S, S_1 , S_2 , S_3 the number of observations recorded in these directions (corresponding to the foregoing sides taken separately); R the resulting distance A B, and ϕ the angle

¹ The following is an extract from a letter of the author, in 1871, on this point: "The question as to the proper mode of discussing winds depends on what we wish to ascertain or point out. If it be to show their sanitary effect, or what winds one is likely to experience at any given place, Lambert's formula is manifestly inadequate, nor was it designed for that purpose. But, if the object be to ascertain in what direction the air, subject to observation, moves as a whole over a given place, it is equally obvious that the only proper method is to resolve its traverse; and to abandon this method would, in my view, put the science back a third of a century. It was the chaotic character of the results that came from the method formerly in vogue, that first drew my attention to the subject, and led me to conceive the idea of resolving the traverse of the winds: ignorant of Lambert's formula, as well as of the fact that Prof. Kaemtz was doing the same thing. The soundness of the principle seemed so obvious, and the results of its application so satisfactory, all over the globe, that I had not supposed it possible that it could ever be called in question."

² See his reduction of Dr. Kane's Arctic observations, published in the Smithsonian Contributions to Knowledge, Vol. XI.

B August, 1875.

which the direction of A B makes with the meridian at B, or $(\phi + 180^{\circ})$ the angle which it makes at A; then we have

tang.
$$\phi = \frac{S \sin \theta + S_1 \sin \theta_1 + S_2 \sin \theta_2 + S_3 \sin \theta_3 \text{ etc.}}{S \cos \theta + S_1 \cos \theta_1 + S_2 \cos \theta_2 + S_3 \cos \theta_3 \text{ etc.}} = \frac{a}{b}$$

putting for the sake of brevity the sum of the terms in the numerator equal to a and of those in the denominator equal to b.

"The value of ϕ , expressed in the ordinary method of reading bearings with reference to the four cardinal points, is given in the tables in the fifth column from the right, and as the numerical value of the tangent of ϕ is the same for angles in each of the four quadrants, recourse must be had to the algebraic signs of the numerator and denominator. If both are +, the direction is in the northeast quadrant; if the numerator is + and the denominator -, it is in the southeast quadrant; if both are -, it is in the southwest quadrant; and if the numerator is - and the denominator +, it is in the northwest quadrant; thus:-

				a	b
Northeast qu	aadrant			+	+
Southeast	66			+	_
Southwest	66			_	
Northwest	66			_	+

Also we have

$$R = \sqrt{a^2 + b^2} = \frac{a}{\sin \phi} = \frac{b}{\cos \phi}$$

the last two forms being the most convenient for computation. the values of $\frac{R}{n}$ are given in the tables in the fourth column from the right.

"Where the places of observation are isolated, resultants are computed for each separately; but where there are several in the same vicinity, they are often grouped together, and the resultants for the group only computed. The observations made at the different stations in a group are ordinarily combined by simply adding them together, in the same manner as if they had all been made at one station; but it did not seem best to adhere uniformly to this method. Suppose, for illustration, that the group consists of but two places, and that the number of observations made at them is very unequal, at each of which the number of observations is sufficient to determine the character of its winds; but that, owing to local influences, the results at the two differ widely. Now if the number of observations at the two places was nearly equal, their sum would afford a tolerable mean between the two; but if very unequal, the place which had the greater would have more weight than properly belonged to it, and a more reliable resultant could be obtained, either by equalizing the numbers representing the observations, or by computing a new resultant from the separate ones of the two places. On the same principle, when in any group, or at any place, the number of observations in the different seasons of the year differ materially, the resultant for the year is computed, not from the sum of all the observations, but from the resultants for the separate seasons.

"The method of computing monsoon influences, or the forces which deflect the wind from its mean annual direction in the different months or seasons of the year,

is as follows: It is assumed that if no such forces existed, the mean direction and relative progress of the wind would be the same for each month of the year, and equal to one-twelfth of the mean annual progress. If, therefore, according to the usual method of applying the 'parallelogram of forces,' we make the progress in any month the diagonal of a parallelogram, and one-twelfth of the mean annual progress one of the sides, either of the contiguous sides will represent the deflecting force, both in quantity and direction. Thus, for example, at Amherst, Massachusetts, Fig. 2, the resultant for January reads N. 69° 42′ W. .36, and for one-twelfth of the mean for the year, measured on the same scale, N. 73° 13′ W. .30. Draw A B in the direction N. 73° 13′ W. and make its length .30. Also draw A D in the direction N. 69° 42′ W. and make its length .36. Complete the parallelogram,

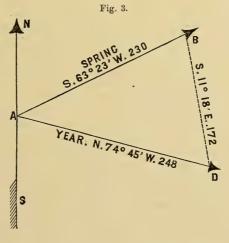

and the side AC or BD will show the direction and amount of the deflecting forces, viz., N. 52° 47′ W., .0632; or a little more than one-fifth as great as the force which determines the mean annual resultant. This value is given in the tables in the second column from the right under the head of 'Force' of monsoon influences.

"Figure 3 shows the same for seasons, where, as in the case of Easton, Pa., the resultant for the spring is represented by A B, which is S. 63° 23′ W., length .230;

and that for the entire year by A D, N. 74° 45′ W., length .248; D B is the monsoon influence, which is from S. 11° 18′ E., length .172. For the most part the deflecting forces are approximations, determined, with tolerable accuracy, by mechanical construction upon a large drafting scale, though in a few cases they were computed trigonometrically, as in the examples here adduced." * *

An inspection of Plate 26 will give a more full illustration of the mode of construction and delineation of these forces, as well as show how their computation afforded a ready test of the accuracy of the computations of the resultants from which

they were derived, for these forces must be in equilibrio, however diverse their separate directions and amounts; were it not so, the particle of air at the end of the months and seasons that constitute its annual course would not be found at the same point that was indicated by the resultant for the year.

On pages 50-51 is a list of authorities cited; to this Professor Coffin intended to add the names of many who had aided him by making or transmitting records of observations. This is an omission that cannot now be supplied. A pencilled statement records his acknowledgment of aid from Dr. Franklin B. Hough, of Albany, N. Y., and grateful mention of President Cattell, and his associates in the Faculty of Lafayette College, for their constant sympathy and encouragement in the work; particularly in services rendered in translations from foreign languages by Prof. Francis A. March, LL.D., and Prof. Augustus A. Bloombergh, Ph.D., also to Prof. Theodore F. Tillinghast, Mr. Thomas C. Green, of Mechanicsville, N. Y., Prof. J. D. Whitney, of Harvard College, the Rev. David Craft, of Wyalusing, Pa., the Rev. John S. Woodside, of Kapurthala, India, and the Rev. Stephen Bush, of Waterford, N. Y., for aid; and to Mr. Henry Mansfield, of Easton, for care in computing the monsoon influences, most of which were drafted by him.

Professor Coffin records the fact that this work lacks observations known to have been made at the following places, but which he failed to secure, viz.:—

Barbacoas, Venezuela, 1852 and 1854. Firmagungulum.
Gaboon Station, Africa.
Leon, Nicaragua, May and July, 1849.
Manilla.
Ponce, Porto Rico.
Singapore.

At the time of the death of Professor Coffin, in 1873, Series A, and the General Tables, Series B, were mainly completed. Though all the pages of the latter Series were numbered in manuscript, here and there were blanks left to be filled. In the observations from Spain, India, and many places in Zones 10 to 18, the trigonometrical work and monsoon influences remained to be computed. No Plates had been prepared.

The supply of these deficiencies was undertaken by his son and successor in the College, Professor Selden J. Coffin. He devised and drew the plates, added the Numerical Index to Stations found in Series A, pages 52-66, revised the entire work, and read the proofs. He also prepared Series C, Velocity Tables, pages 637 to 654, and made the deductions connected with them.

This work has been executed with a feeling of pious regard for the memory of a venerated parent, interest in science, and a devotion which merits special commendation.

The Institution also availed itself of the meteorological knowledge and power of original investigation of Dr. Alexander J. Woeikof, Secretary of the Meteorological Committee of the Imperial Geographical Society of Russia, during his late visit to this country, for a series of deductions and analyses from the tables and charts, which the untimely death of Professor Coffin prevented his undertaking. These discussions and analyses are found on pages 623 to 714, and are wholly from the pen of Dr. Woeikof, who also supplied the material in the form of "Addenda" at the end of the respective zones, and carefully revised the whole work.

PREFACE.

For the better illustration of Dr. Woeikof's discussion, three plates have been reproduced from the important paper by Alexander Buchan, in the Transactions of the Royal Society of Edinburgh, and for which acknowledgment is here made. These plates exhibit by isobaric lines the mean pressure of the atmosphere over the earth for the year, and for January and July.

This work is given to the world with confidence that it will be an acceptable contribution to science, worthy of the Smithsonian Institution, and a permanent memorial of one who cheerfully devoted to its preparation much of the energies of a long life.

JOSEPH HENRY,

Secretary S. I.

Washington, November, 1875.

¹ The mean pressure of the atmosphere, and the prevailing winds over the globe for the months and for the year, Part II., by Alexander Buchan, M.A., Secretary of the Scottish Meteorological Society.—Trans. of the Royal Soc. of Edinb., vol. xxv. 1869.

INTRODUCTION.

ORIGIN AND PREPARATION OF THE MEMOIR ON THE WINDS OF THE GLOBE.

COMMUNICATED BY PROFESSOR SELDEN J. COFFIN.

The decease of Professor Coffin occurred before he had prepared any descriptive text of this work, save what is given in the Preface, and therefore a monograph found among his papers has special interest, as intimating the probable line of treatment he would have pursued, and indicating topics of research in which he was engaged, or to which his attention had been directed. It appears to be the substance of a statement made to the National Academy of Sciences about two years prior to his death. The title is, "A History of the Present Condition of an Investigation of the Winds." Its contents, somewhat abridged, are as follows:—

"This is not intended as a formal communication on the Winds, but rather a brief narration of what I have accomplished, after having been engaged for many years in the investigation of the laws that govern the circulation of the atmosphere over the earth's surface, with the attendant phenomena.

The following are the problems investigated:-

1st. What is the mean direction of the wind over the different parts of the earth's surface? Or in what direction does the air, as a whole, move over them?

2d. What is the progressive motion of the air in this mean direction? Or, if data be wanting for determining this in *miles*—and we assume that the average velocity of winds from all points of the compass is the same—during what proportion of the *time* must the wind blow in this mean direction, so that if the remainder of the time were occupied by calms, or by winds whose conflicting movements neutralize each other, the resulting general progressive motion of the air, as a whole, would be the same as it now is?

3d. What is the direction and amount of the force that deflects the wind from its mean annual direction in any given month, or season of the year? Or, in other words, what must be the direction of a wind during any given month or season of the year, and during what proportion of the time must it blow, so that combined with the movement of the air in its mean annual direction, it may afford

a resultant the same as that for the month or season? The former may be regarded as the wind that would exist if the surface of the earth were homogeneous, and the sun ever over the equator; and the latter as that which is due to the change of temperature in the different parts of the year, in connection with the character of the neighboring regions, chiefly with respect to land and water. These deflecting forces, which are found almost everywhere, I denominate monsoon influences, and where they are so great as to decidedly control the direction of the current, the resulting winds are the well-known monsoons.

4th. What relation exists between the direction of the wind and the pressure of the atmosphere? Or, what winds are, on an average, attended by a rise in the barometer, and what by a fall, and at what average rate?

5th. Also what connection exists between the direction of the wind and the pressure, temperature, and humidity of the atmosphere, the state of the sky, and the amount of rain-fall?

"These are not the only questions of interest connected with the study of the winds (for their relations to hygicnic and agricultural considerations merit close investigation), but they are the only ones to which I have given much attention. And, as to the latter, my investigations have been confined chiefly to the point first named in it.

"The proper scientific investigation of each of these questions is comparatively of recent date, extending back not much further than the year 1830. Vast collections of observations on the winds had been made previously, which are now of invaluable service under the improved methods of studying them; and some of the more obvious phenomena, such as the 'trade winds,' monsoons, and regions of calms, were well known. But the usual, and indeed the only method of discussing observations of the winds, was to sum up the number that was observed from each of the several points of the compass, to regard that direction which afforded the largest sum as the prevailing direction, and to make no account of the rest. This method often served to point out the geographical features of the surrounding country, rather than to afford any information of value in regard to the real question discussed. It was about the year 1836, perhaps a little earlier, that the idea of resolving the traverse of the winds on the principle now so familiarly known as Lambert's formula, first occurred, nearly simultaneously, to Prof. Kaemtz in Europe, and to Prof. Loomis and myself in this country, to each without the knowledge of the others. [This method is fully described and the formulæ stated in the Preface to this work.]

"My first efforts were directed to the winds at Dartmouth College, New Hampshire, as then reported monthly in the *Vermont Chronicle*, 1836, and having soon afterward removed to Ogdensburg, New York, I applied the method to the winds there, as recorded momentarily by a self-registering vane that I had constructed for the purpose. The results at the latter place were published in the annual report of the Regents of the University of the State of New York for the year 1838.

"In the year 1824, the Legislature of New York had made an appropriation for establishing a system of meteorological observations at different academies in the State, the tabulated results of which were, for many years, published annually in the Reports of the Regents. In preparing these tables, the prevailing direction of the wind was computed in the then common though imperfect manner already described, and the results were as chaotic as can well be imagined. I concluded to try the new method upon them, and the results were published in the Regents' Report for 1840, accompanied by a note from the Secretary of the Board, inviting special attention to them. They were of the most satisfactory character, and when mapped showed the course of the dominant current of air over the State, with occasional deflections, dependent upon the geographical features of the adjacent country, as clearly defined as the courses of the Hudson or the Mississippi rivers. Encouraged by this, I undertook the task of collecting observations on winds over the entire extent of the United States, which was then no easy matter, as there were no such instrumentalities, to aid in the work, as are at present accomplishing so much—the Smithsonian Institution and National Observatory not being in existence, and the only collection of observations, covering any wide extent of country, was that at the Surgeon General's Office in Washington. This had been commenced under the Surgeon General, Dr. Lovell, in the year 1822, and consisted of registers kept at different military posts, and others that had been forwarded there at the request of the late Prof. James P. Espy, who was then connected with the office. None of the latter had been published, and of the former, only those for the first nine years, and embracing only from eleven to twenty posts, the number differing in different years. The rest was all in manuscript, unpublished and unreduced. My attention was called to this collection by the late Col. J. J. Abert, Chief of the Topographical Bureau, who, in 1839, invited me to visit Washington for the purpose of inspecting it. Here I was not only allowed free access to all the manuscript material in the office, which I spent several weeks in examining and reducing, but when I left, I was permitted to take home with me all the more valuable registers of Mr. Espy's collection, indeed all that I desired, and to make the requisite computations from them there. Beyond what I thus obtained, I was dependent almost solely on private correspondence for the means of prosecuting my proposed work.

"It was while engaged in slowly collecting material that, at a meeting of the American Association of Geologists and Naturalists, held at New Haven, in 1845, I was appointed a committee to report on the present state of our knowledge of the winds of North America and the North Atlantic Ocean. This greatly enlarged my field of labor, and as I knew that I could obtain material such as I wanted from many European countries, I concluded to enlarge it still further, and make it embrace the entire northern hemisphere.

[For this purpose he availed himself of all the materials relative to meteorology found in the libraries of New York, New Haven, Philadelphia, Princeton, and Washington. As much of this material was unreduced, he was obliged to spend a considerable portion of time at each of these places in the performance of this work.]

"Observations of the winds at several places in Persia, Syria, Palestine, and at Constantinople, were kindly made at my request, for a year or two, by missiono December, 1875.

aries residing there, and forwarded to me in manuscript. Officers of the British Hudson's Bay Company were so kind as to copy for me in manuscript the entire series of observations on winds at several of their posts in the remote parts of British America—at one of them for a period of seven years. To secure observations at sea I was aided by the late Gerard Hallock, Esq., one of the editors of the Journal of Commerce, in making arrangements with ship-owners in New York, for the loan of the logs of their different vessels. I had not, however, proceeded far in this latter line of research, when Lieut. Maury commenced his labors in the same direction at the National Observatory; and his facilities for procuring material were so superior to mine that I relinquished the field to him, and relied on his published charts for the data I needed at sea, except in the latitudes above 60°, beyond which his charts did not extend.

"It was not till three years after the date of my appointment by the Association that I was prepared to report, which was at the first meeting of the American Association for the Advancement of Science, at Philadelphia, in 1848; the body which appointed me having in the mean time changed its organization and name to that just given. The report, derived from a period of over 2000 years of observation at 550 stations, contained the announcement 'that between north latitude 33½° and 60° there is a general current from a little to the south of west, extending entirely around the globe; but that, as those limits are approached, it gradually loses its decided character, and at the limit, on either side, all trace of any fixed direction disappears, the current at any place being controlled entirely by local influences, as illustrated in the winds of Augusta, Georgia. After passing the limit on the south, a current from the opposite direction sets in, which, as we go south, gradually assumes a more decided character, till we come fully within the limits of the trade-winds. North of latitude 60° there are indications that a uniform current that comes down from the north, in the polar regions, veers towards the west, thus establishing a third system, which breaks up at about latitude 60°.' It was while preparing this report, and by applying the improved method of investigation to the winds in the high northern latitudes, that the interesting discovery was thus made of the system of the polar winds, entirely distinct from those which prevail south of it, the physical causes of which have since been so admirably demonstrated by Prof. Ferrel, and which is now beginning to be generally recognized as a valuable contribution to meteorology.

"I may here remark that when first announced all the evidence I had of the existence of the polar system of winds was derived from observations made in the northeastern portions of the American continent, Greenland, Northern Iceland, Northern Spitzbergen, and the seas adjacent; the limit attaining so high a latitude on the eastern continent that only the extreme north of Europe and Northern Siberia fell within it, and I was not able to procure reliable data from these inhospitable regions. I have, however, since obtained an abstract of the observations of Lieut. Anschu, for nearly two years, made on the shore of the Arctic Ocean, in Siberia, and valuable material from several places in Northern Finland, Southern Spitzbergen; from Kane, Hayes [and Hall], in the Greenland Seas; and also from the vicinity of Behring Strait on both sides, contributed by parties employed

in explorations for the Russo-American telegraph line. The results of all these observations, with the exception of those of Dr. Kane, at Van Rensselaer Harbor, are in accordance with the doctrine in question. And in regard to these latter, which are utterly discordant, it is worthy of remark, that while the mean direction of the wind is almost diametrically opposite to what it is at Port Foulke, only a few leagues distant, the progressive motion in the mean direction is very small, indicating local disturbance. For I have found, as a very general rule, the world over, that wherever, from local causes, the atmospheric current is diverted from its mean course, the progressive motion is reduced. Northeastern Asia merits a more careful study, and I have long made efforts to procure observations therefrom, but without any prospect of success, until 1869, when I was so fortunate as to receive from the Meteorological Committee of the Geographical Society of Irkutsk, in Eastern Siberia, an offer of co-operation. It is still difficult to obtain the requisite observations, as the region to be studied lies north of all the settled parts of Siberia, and aid can probably be had only from missionaries of the Russian church, stationed at some of the settlements on the rivers flowing into the Arctic Ocean. In respect to these localities I acknowledge aid received through the kindness of Col. Thomas W. Knox, of New York, and George Kennan, of Norwalk, Ohio.

"In the same report, above named, I pointed out and illustrated the peculiar 'S-shaped' curves described by the wind in its mean course for the different months or seasons of the year, on both sides of the Atlantic, though I was not then prepared to fully explain them, nor did I perceive the interesting conclusions about to be deduced from them. [Illustrations of these curves are found in Plate 26, which also exhibits the graphical method of deriving from them the monsoon influences, which determine the direction and amount of their curvature. The manner of computing them is explained in the Preface.]

"The results reached in this report, with the data from which they were derived, forming a quarto volume of 200 pages, were subsequently published in the Smithsonian Contributions to Knowledge, constituting a part of Vol. VI. This, though as perfect as the materials known could make it, and pointing out truths of importance never before recognized, was, as was soon perceived, not what it ought to be. On sending it abroad the meager filling up of portions of the eastern continent was noticed, and persons residing there kindly lent their aid in procuring material to fill them. Among these I may mention particularly Chevalier Kahnikoff, Mr. Wesselesky and Prof. Kaemtz of Russia, and Prof. Buys Ballot, Director of the Royal Observatory of Holland, from whom collectively I received records from not less than one hundred new places; and by the exchanges and collections of the Smithsonian Institution many more were added. Subsequently additional offers of aid were received from the eminent European meteorologists, Alexander Buchan, of Scotland, Dr. Alexander J. Woeikof, of Russia, Baron Meydall, and Messrs. Aguilar and Mack. In the mean time in this country, the acquisition of California, New Mexico, and Arizona largely increased the number of military posts at which observations were taken, while by the active efforts of the Smithsonian Institution there was secured a vast number of new observers in all parts

of the country, and many of them at points very remote. Lieut. Maury was also prosecuting his work on the seas, and had covered by his published charts, the entire Atlantic and Indian Oceans, the South Pacific, and all the North Pacific except a portion of comparatively small area, between the meridians of 150° E. and 165° W. from Greenwich, the chart for which was referred to by him in his latest report as 'not yet printed'; -implying that it was substantially complete in manuscript, and, if so, it would seem very desirable to have it completed and published.

"In view of all these facts, and also that my original work lacked scientific arrangement, it was thought desirable to revise and enlarge it, and the Smithsonian Institution generously made appropriations to aid in the computations, as well as put at my disposal all the material at its command. The plan proposed for the new work was that followed in the present treatise, to divide the earth into 36 zones, by parallels of latitude 5° asunder, and so extending from the north to the south pole; in each of these zones commencing at the 180th meridian from Greenwich, and proceeding easterly according as observations furnished the data, around the earth to the same meridian again. Between the parallels of latitude 60° N. and 60° S. where observations are more abundant, records have been obtained from about 2000 places in North America and the West Indies, 27 in South America, 23 at islands in the Atlantic, over 700 in Europe, 206 in Asia and the East Indies, 70 in Africa, 48 in Australia and islands of the Pacific and Indian Oceans, including the extreme 'southerly ones of Kerguelen's Land and Heard's Island—the most southerly points where man has remained for any considerable length of time; and for over 1000 years at sea. If this area be divided into geographical squares, by drawing meridians and parallels of latitude 5° asynder, of the 1728 squares so formed, 1492 are represented in the contents of The 326 vacant squares from which no observations have been this work. obtained are as follows:-

21 in North America, mostly in British America,

40 in the interior of South America,

None in Europe, 75 in Central Asia,

66 in Africa,

15 in the interior of Australia,

108 in the North Pacific Ocean, and

1 in the South Pacific Ocean.

North and south of the parallels of 60°, it is more difficult to obtain observations, and the material is therefore less abundant. Between 60° and 65° N., results are given for 57 stations, embracing a period of 316 years, mainly in Northern Russia. Further north, about 34 stations have been obtained; so that all these 36 zones are represented in the work except three, one about the north pole and two about the south, which had never been visited by man.

I had proceeded so far with the work in the southern hemisphere that, in 1859, I read a paper at the meeting of the American Association at Springfield, Mass.,

in which I showed that observations clearly indicated, and, indeed, all but demonstrated, the existence of a system of winds about the south pole, and extending from 25° to 30° from it, analogous to that which had been proved to exist about the north pole. Although the visits of explorers to this inhospitable region had been limited to periods of a few days each—too short a time for any well-defined results—yet the observations disclosed the remarkable fact that while in the contiguous zone further north, and between it and the trade-winds, the mean direction of the wind was always from some point between N. and N. W., with most wonderful uniformity, far more so than in the northern hemisphere, owing undoubtedly to the less amount of land to obstruct its passage, yet out of fifteen visits by explorers to as many different points in this southern polar zone, in none was the wind from any point in the N. W. quarter, a series of coincidences without a parallel, if merely accidental, and no such system exists.

[Next, in this monograph, occur the author's remarks on the influence of difference of velocity in modifying the mean direction of the wind, which have been placed on pages 637-639, in the introduction to the Velocity Tables. Though a longer time would be desirable, the discussion is limited to observations for a period of four years, owing to the great labor and expense of making the com-

putations.]

"The discussion of the remaining point named as belonging to the investigation, viz., the connection between the direction of the wind and the rise or fall of the barometer, may not be prepared for appearance in my new work, though it is not inferior in point of interest and practical value to either of the others. It was commenced in its present form about the same time as that of the mean direction of the wind (1836-8), and, like that, nearly simultaneously in Europe and in this country, neither party having any knowledge of what the other was doing. Inquiries had been previously instituted as to the direction of the wind which usually attended a maximum or a minimum pressure of the atmosphere, and statements had been published in England, and in this country also (?), that the former was N. E. and the latter S. W.; but the far more important question was, "What change takes place in the barometer during the continuance of different winds?" And it was to this point that the new investigation was chiefly directed. The statements just quoted may be true, but the inference drawn by some therefrom, that winds from the former point tended specially to raise the barometer, and those from the latter to depress it, was not well founded. It was as though the astronomer should conclude that the difference between the mean and true motions of a planet is greatest about midway between the apsides of its orbit, because the equation of the centre is greatest there. If winds from the west, northwest, and north tend to raise the barometer, and those from the east, southeast, and south tend to depress it, and if the wind is prone to shift its direction in the order just named, it is obvious that when it reaches the N. E. point, the barometer must show the accumulated effects of all the winds through the preceding 180 degrees, and so of course stand high, although the N. E. wind itself were neutral in its influence. To study the question properly, we need either self-registering instruments (both barometer and wind-vane), or very frequent observations; and consequently there are but few places where we have the requisite data. The former of these instruments it has been found difficult to construct so as to work satisfactorily.

"My first effort as to the problem was made in the year 1837, at Ogdensburg, N. Y., where I erected a self-registering vane, and made arrangements for frequent observations of the barometer. The definiteness of the result surprised me. It divided the horizon into two perfectly distinct portions, the winds from one of which were attended with an average rise of the barometer, and those from the other with a fall. And although my vane registered from 32 points of the compass, there was no intermingling of the points in the result. But was the law that I had thus discovered, a general one? Or, was it owing to something peculiar to that locality? To test this, I proceeded to make similar computations for twelve other places in this country and elsewhere, according as the observations to which I had access furnished data applicable to the purpose, and while so employed I found that Prof. Dové, of Berlin, had done the same for five places more, which I united with my own, making eighteen in all. [These are delineated in Plate 23.]

"Early in these investigations the question arose whether the results favored the rotary or centripetal theory of storms; the indications were that the motion was both rotary and centripetal. I was not then fully prepared to submit what I had offered for publication, except in outline, and I deferred to do so. Since 1853 I have added nothing to it, except the results of Dr. Louis Berlandier's observations at Matamoras in Mexico. The following gives in a tabular form the results of all the observations since that date:—

"Regarding the rate of rise or fall in the barometer during winds from each point of compass, given in the preceding table, as the measure of the force that produces it, and reducing these forces to a single force, in the usual way, we obtain the results in the second, third, and fourth columns of the following table; to which I have added, in the fifth column, the mean direction of the wind.\"

The arrows within the inner circle of the Barometrical Wind-roses [Plate 23] exhibit these results to the eye.

TABLE II.

POINTS OF MAXIMUM AND MINIMUM PRESSURE.

Place of observation.	Point of maximum pressure.	Point of minimum pressure.	Mean line of maximum and minimum pressure.	Mean direction of wind.

- "The results shown in the foregoing tables and diagrams confirm all that I had previously adduced, and establish conclusively, I think, the following facts, at least in the zones of westerly winds.
- "1st. That the horizon is divided by nature into two well-defined portions, the winds from between the division points on the one side being all attended with a rise in the barometer, and on the other with a fall. This is found true at all the stations where there are reliable observations. Even where they are taken for thirty-two points of the compass, there is no intermingling.
- "2d. That in the northern hemisphere, one of these points lies in a southwesterly direction, and the other in a northeasterly. Barnoule in Siberia, and Sitka in Alaska, look like exceptions; but at both these places the results were computed

¹ The observations at sea were taken in various latitudes, and those on the direction of the wind not reported; so that it was impossible to know accurately what mean direction to assign. But taking into account the circumstances of the voyages during which they were taken, I have assumed, as approximately correct for the southern hemisphere, one that I computed from a zone on Lieut. Maury's charts, extending from lat. 40° to 45° S., and from long. 20° E. to 120° W.; and for the North Atlantic, one deduced from about twelve years' observations, taken north of lat. 36°

for a short time only, and might be somewhat modified by making use of a longer series of observations. It is probable, moreover, as I have shown elsewhere, that Sitka lies without the zone of westerly winds, and where a different law may prevail.

"3d. That the line of its approach generally makes an angle, more or less acute, with one drawn to the point of maximum pressure.² The only exception is at Hamilton,³ Bermuda, where it is slightly obtuse (92° 40'). Nor is the result different, if, instead of regarding the mean resultant of all the forces which raise the barometer as the point of maximum pressure, we (perhaps more properly) regard each fall as a negative rise, and *vice versa*, and then obtain one mean resultant for the whole. The fourth column in Table II. was computed in this way, and the results are shown on the Barometrical Wind-roses [Plate 23] by a broken line. [For application of this discussion to the storm-curve, see author's article on pp. 89–101, Proceedings of the American Association for the Advancement of Science, Cleveland, Ohio, 1853.]

"The plan of the 'Winds of the Globe' contemplated giving resultants at each place, for each month and season, with monsoon influences for the seasons. The work would be much more perfect, if this could be done in all cases, but the magnitude of the labor forbade it. For a like reason, as well as to render it possible to represent the results on maps, it was thought judicious to group the places of observation by districts, where they were numerous, instead of making computations for each place separately. With the facilities we have devised, in the way of special tables to aid in the computations, we have found that where observations, recorded for 16 points of the compass, have been collected and properly arranged for computation, an active computer can calculate about 35 resultants in a day. When the observations are recorded for 32 or more points of compass, the labor is of course much greater, but there are comparatively few such. On the other hand, there are many where they are recorded for only 8 points. If we include the calculation of the monsoon influences, which has been done chiefly by plotting, the average per day will not exceed the number just named."

[The exact state of forwardness of the work at the time of Professor Coffin's decease is fully related in the preface.]

¹ One month at Sitka, and two at Barnoule.

² Further on, in the same article from which these conclusions are quoted, and which may be found on page 89 of the Proceedings of the American Association for the Advancement of Science, 1853; Prof. Coffin determines this angle as 65°; and a reference to the article plainly shows that this determination was reached, without any knowledge by him of its having been accomplished, or even attempted, at that time, by any other writer on the subject, although the reference on page 664, of this work, conveys the intimation that this principle is generally referred to in Europe as "Buys-Ballot's Law of the Winds". But it does not there appear at what date Prof. Ballot had made the announcement, with which he is so accredited.

^{· &}lt;sup>3</sup> It is worthy of remark that here, too, the angle is acute, if, instead of the mean direction of the wind observed at Hamilton, we employ that at Ireland Isle, another island in the same group, or even the mean between the two.

December, 1875.

WINDS OF THE GLOBE.

SERIES A. ALPHABETICAL LIST OF STATIONS.

The following list will serve as an *index* for finding where the results of the material from any given station are incorporated into the work, by turning to the number of its zone as given in the running title at the top of each right-hand page, and following the serial numbers down till the one belonging to that station is reached. For example, if it be required to find the results of the observations made at Jerusalem, turn to zone No. 12, and follow its serial numbers down to 179.

NUMERICAL INDEX TO STATIONS.

ZONE 1. Lat. 85° to 90° N.

No stations.

ZONE 2. Lat. 80° to 85° N.

- 1. Smith's Strait, long. 65° to 75° W.
- 2. Arctic Ocean, long. 5° to 25° E. 3. Arctic Ocean, long. 7° to 17° E.

ZONE 3. Lat. 75° to 80° N.

- Northumberland Sound.
 At sea, long. 90° to 97° W.
 Port Refuge.
- At sea, long. 80° to 90° W.
 At sea, long. 70° to 80° W.
- Port Foulke.
- Rensselaer Bay.
- 9. Raffin's Bay, long. 58° to 70° W.
 9. At sea, from Greenland to Spitzbergen, long. 17½° W. to 23° E.
 10. Magdalena Bay.
 11. Heela Cove.
- 12. Northern Spitzbergen.
- 13. Bell Sound and Slaadberg
- 14. Henlopen Straits and Eastern Spitzbergen.

ZONE 4. Lat. 70° to 75° N

Western Arctic Ocean and its Islands.

- 1. Arctic Ocean, long, 155 to 175° W.
- and 3. Baring's Island.
- 4. Melville Island.
- 5. Dealy Island.
- 6. Assistance Harbor.
 7. Felix Harbor, Boothia Felix.
 8. Sheriff's Harbor, Boothia Felix.
- 9. Southeastern Boothia Felix. 10. Port Kennedy.
- 11. Port Bowen.
- 12. Arctic Ocean, long. 80° to 110° W. 13. Baffin's Bay, long. 60° to 80° W. 14. Baffin's Bay, long. 50° to 60° W.

- 15. Upernavik.

Northern Europe and Asia.

- 17. Bear Island, near Spitzbergen.
- 18. Hammerfest.
- 19. Vardo.
- 20. Arctic Ocean, long. 20° to 40° E. 21. Nova Zembla.
- 22. Arctic Ocean, long. 75° to 90° E. 14. Friederichthal.

ZONE 4 .- Continued.

- 23. Taimurland
 - (Great Northern Tundra). Korennoje Filipooskoje.

- 25. Ust Yansk.
 26. Arctic Ocean, long. 130° to 170° E.
 27. Bear Island (northern coast of Siberia).

ZONE 5. Lat. 65° to 70° N.

- 1. At sea.
- 2. Port Clarence & Kotzebue Sound.
- 3. Fort McPherson. 4. Fort Anderson.
- 5. Fort Franklin.
- 6. Fort Confidence.

- 7. Port Hope.
 8. Igloolik and vicinity.
 9. Winter Island and vicinity.
 10. Arctic Ocean.
- 11. Baffin's Bay
- 12. Godthaab. 13. Jacobshavn.
- 14. Eyafiord.
- 15. Stykkisholm.
- 16. At sea, long. 15° W. to 15° E.
- 17. Andennes. 18. Tromsoe.
- 19. Bossekop.20. Muonioniska and vicinity.
- 21. At sea, long. 30° to 40° E.
- 22. Stensele. 23. Iockmock.
- 24. Pitea.
- 25. Haparanda.26. Nijuii Kolymsk and Anadyrsk.27. Bush's Station.

ZONE 6. Lat. 60° to 65° N

- 1. At sea.
- 2. Plover Bay.
- 3. Fort St. Michaels.
- 4. Unalakleet.
- 5. Ikogmut.
- 6. Nulato. 6½. Nos. 3, 4 and 6 combined. 7. Fort Norman.
- 8. Fort Simpson.
- 9. Fort Rae.
- 10. Fort Enterprise, Hudson's Bay Territory.

 11. Fort Reliance, Great Slave Lake.
- 12. Baffin's Bay and Hudson's Strait, long, 45° to 80° W.
 13. New Hernnhutt.

ZONE 6 .- Continued.

- 15. Bessested.
- 16. Reikiavik, 1813 and 1840.
- 17. Reikiavik, 1826-36. 18. Reikiavik, 1866-8.
- 19. Reikiavik, aggregate. 20. Atlantic Ocean, long. 35° W. to 10° E.
- 21. Thorshavn.
- 2. Bressay.
- 23. East Yell.

Norway and Sweden.

- 24. Aalesund.
- Soendmor.
- 26. Dovre.
- 27. Christiansund.
- 28. Drontheim. 29. Bergen.
- 30. Villa. 31. Ostersund.
- 32. Fahlun.
- 33. Gefle.
- 34. Hernosund. 35. Nos. 33 and 34 combined.
- 35 (a). Holmia. 36. Umea.

Finland.

- 37. Aland Islands, Baltic Sea.38. Laichela.39. Storkiro.
- 40. Varo.

GENERAL TABLES

CONTAINING *

RESULTS OF OBSERVATIONS GROUPED IN ZONES OF LATITUDE OF 5° EACH, AND ARRANGED IN EACH ZONE BY SERIAL NUMBERS, IN THE ORDER OF THE LONGITUDES OF THE RESPECTIVE PLACES, BEGINNING AT 180° FROM GREENWICH, AND PROCEEDING EASTWARD AROUND THE GLOBE.

WINDS OF THE GLOBE.

SERIES B. GENERAL TABLES.

ZONE No. 1.

LATITUDE 85° TO 90° NORTH.

This zone having never been visited by man, direct observations of its winds are wanting, and their character must necessarily be very much a matter of conjecture. It can only be inferred very obscurely from that of those in the contiguous zones. If ever the north pole is reached, the wind there may perhaps more probably be found to blow from the direction of the Eastern Siberian polar seas, towards Iceland, on the west of Europe.

ZONE No. 2.

LATITUDE 80° TO 85° NORTH.

The materials for the study of the winds of this zone consist of the observations of Dr. Kane and his party, for five days in the summer of 1854, on the eastern shore of Smith's Strait, those of the German Polar Expedition north of Spitzbergen for four days in July and August and five in September, 1868; those of Parry from June 25 to August 10, 1827, on the ice north of Spitzbergen,—periods of time too short to afford any very reliable results; and those of Captain Hall's party from November 6, 1871, to August 15, 1872. In May, 1861, Dr. Hayes and party spent ten days in this zone, on the western shore of Smith's Strait, but do not appear to have taken note of the direction of the wind to any great extent. With the exception of Captain Hall's command, that spent the winter of 1871–2 in latitude 82° 16' N. in Polaris Bay, no other civilized parties have ever travelled north of the 80th parallel. The observed directions of the wind, and the computed resultants, were as follows:—

(No. 1.) Smith's Strait. Longitude 65° to 75° W.

Observed directions—N. 3, N. E. 1, calm 1; total 5. Direction of resultant N. 10° 50′ E.??? Ratio of resultant to sum of winds .75

(No. 2.) Arctic Ocean. Longitude 5° to 25° E. Summer.

Observed directions—North 6, N. N. E. 2, N. E. by N. 3, N. E. 1, E. N. E. 1. East 9, E. by S. 3, E. S. E. 9, S. E. by E. 3, S. E. 14, S. E. by S. 1, S. by E. 1. South 7, S. by W. 3, S. W. 10, S. W. by W. 1, W. S. W. 5. West 3, W. by N. 2, W. N. W. 3, N. W. by N. 1, calm 3; total 94.

Direction of resultant S. 30° 7′ E.

Ratio of resultant to sum of winds .30.

Number of days 51.

(No. 3.) Arctic Ocean. Longitude 7° to 17° E. Autumn.

Observed directions—S. S. E. 1, S. S. W. 1, W. 1, N. N. W. 1, N. by W. 1.

Direction of resultant, N. 87° 50' W. ???

Ratio of resultant to sum of winds .32.

Number of days 5.

(No. 4.) Polaris Bay, winter quarters of the U. S. Arctic Expedition under CAPT. HALL. Observed from November 6, 1871, to August 15, 1872, by Dr. Bessels.

^{&#}x27; The observations were horary, with some interruptions. They are calculated here for the hours $1\frac{1}{2}$ and $7\frac{1}{2}$ A. M. and P. M. only.

ZONE No. 3.

LATITUDE 75° to 80° NORTH.

The observations in this zone were made by different Arctic explorers for an aggregate period of 3120 days, or more than eight and a half years.

(Nos. 1 to 5.) Western Arctic Ocean (north of America).

Observed at the following places, viz. :-

Northumberland Sound, by Belcher, from August 1st, 1852, to June 30th, 1853.

At sea (longitude 90° to 97° W.) by Kane, Penny, and Belcher in the years 1850 to 1853, for an aggregate period of 96 days.

Port Refuge, Disaster Bay, by Belcher, from August 18th, 1853, to August 23d, 1854.

At sea (longitude 70° to 90° W.), by Ross, for 10 days in the summer of 1818; by Snow, for 4 days in the summer of 1850; by Kane, for 33 days in the spring and summer of 1850, and summer of 1853; and by McClintock, for three days in the autumn of 1857, and for 10 days in the summer of 1858; making an aggregate of 60 days. The observations in spring were made between the meridians of 80° and 90°, and those in summer and autumn between 70° and 80°.

(Nos. 6, 7, and 8.)

Northern Greenland.

Observed at the following places, viz. :--

Port Foulke, by Isaac I. Hayes, from September 1st, 1860, to July 31st, 1861.

Rensselaer Bay, under direction of Elisha Kent Kane, from September 1st, 1853, to Jan. 24th, 1855. Lifeboat Cove, under Capt. Hall, from Nov. 1, 1872, to May 31, 1873. Observed by Dr. Bessels.

I Computed from the resultants for the seasons.

At Port Foulke and Rensselaer Bay the estimated velocity of the wind was indicated by a scale of numbers extending from 1 to 10, as follows:—

No.	Character of winds.	Pressure in pounds per square foot.	Velocity in miles per hour.	No.	Character of winds.	Pressure in pounds per square foot.	Velocity in miles per hour.
0 1 2 3 4 5	Calm Light air	0.005 0.008 0.09	0 1 4 13 23 32	7 5 9	Fresh gale Strong gale Storm Tempest Hurricane	7.9 12. 18. 31. 49.	40 50 60 80 100

The observations at both places were discussed at the expense of the Smithsonian Institution, by Charles A. Schott, of the U. S. Coast Survey, who arranged and classified them, and computed the second series of resultants at each.¹

(Nos. 9 to 15.) Baffin's Bay, Eastern Arctic Ocean, and Spitzbergen.

Observed at the following places, viz. :--

Arctic Ocean, longitude 11° 20′ W. to 23° E., by Scoresby for 717 days in the springs and summers of 1807 to 1818; by Parry for 25 days in the spring of 1827; and by the French Commission¹ for 35 days in the summer of 1839.

Baffin's Bay, by Ross for 28 days in the summer of 1818; by Snow for 22 days, and by Penny for 38 days in the summer of 1850; by Kane for 25 days in the summers of 1850 and 1853; and by McClintock for 52 days in the autumn of 1857, and for 52 days in the summers of 1857 and 1858.

Bell Sound, Southern Spitzbergen, by the French Commission for 12 days in July and August, Slaadberg, Southern Spitzbergen, 5 1838.

Heckla Cove, Northern Spitzbergen, by Parry from June 20th to August 28th, 1827.

Maqdalena Bay, Northern Spitzbergen, by the French Commission for 12 days in August, 1839.

Remarks.—The observations made in this zone, though much more abundant than in the preceding one, are still too meagre to afford results that can be confidently relied upon. Of the thirty resultants, computed for seasons, taking into account only the relative length of time during which the several winds prevailed, thirteen are from the N. E. quarter, three from the S. E., eight from the S. W., and six from the N. W. Only four places—Northumberland Sound, Port Refuge, Port Foulke, and Rensselaer Bay, afford data for computing the resultant for each season of the year, and hence for the whole year. At two of these the annual resultant is northeasterly, at one southeasterly, and at one southwesterly. At Port

¹ The meteorological observers connected with this expedition were Professors C. B. Lilliehook, Charles Boeck, and J. Durocher, and Messrs. V. Lattin, A. Bravais, P. A. Sliljestrom, J. Gennet, E. Normand, C. Martins, A. Fleurist de Langle, U. W. de Gyldenstolpe, R. Angles, J. de la Roche Poncie, G. Ferré, A. de Chastellier, A. Fabvre, E. Pottier, and N. de St. Vulfram.

² Nos. 11 and 12 combined.

³ The resultant for this season is obtained by combining the observations of Parry for 25 days, as given in the text, with those of Scoresby for 371 days, which are as follows, viz.: N. by W. to N. N. E. 892, N. E. by N. to E. N. E. 445, E. by N. to E. S. E. 243, S. E. by E. to S. S. E. 277, S. by E. to S. S. W. 250, S. W. by S. to W. S. W. 185, W. by S. to W. N. W. by S. to W. N. N. W. 661, calm or variable 501.

⁴ The resultant for this season is obtained by combining the observations of the French Commission for 35 days, as given in the text, with those of Scoresby for 346 days, which are as follows, viz.: N. by W. to N. N. E. 567, N. E. by N. to E. N. E. 232, E. by N. to E. S. E. 191, S. E. by E. to S. S. E. 297, S. by E. to S. S. W. 538, S. W. by S. to W. S. W. 417, W. by S. to W. N. W. 218, N. W. by W. to N. N. W. 418, calm or variable 672.

Foulke and Rensselaer Bay resultants are also computed for the number of miles travelled by the wind, but they do not differ much in direction from those computed for time only; and at both these places monsoon influence can be perceived. At the former it is southwesterly in summer and northeasterly in winter. At the latter it is northwesterly in summer and southeasterly in winter.

ZONE No. 4.

LATITUDE 70° TO 75° NORTH.

The data for the study of the winds of this zone consist of observations made in the following portions of it:—

1st. Arctic seas of North America and Greenland, and islands in the same, for an aggregate period of more than twelve and a half years, beside the observations on Baring's Island by McClure, which were not regularly recorded, but appear only in the form of incidental allusions.

- 2d. Western Greenland, at Upernavik, for eight years.
- 3d. Arctic Ocean, between Greenland and the coast of Norway, for an aggregate period of 432 days.
 - 4th. Finmark, at two stations, for periods severally of eight and fourteen years.
 - 5th. Arctic Ocean, north of Europe, for two months.
 - 6th. Eastern part of Nova Zembla for four and a half years.
- 7th. Northern Siberia and the adjacent seas for an aggregate period of over two and a half years, besides numerous notices and remarks by Wrangel in regard to the winds of this part of the Arctic Ocean.

The aggregate length of time during which observations were regularly recorded in this zone, and incorporated into this work, is therefore over 51 years.

(Nos. 1 to 14.) Western Arctic Ocean and its Islands.

Observed at the following places, viz.:-

At sea (longitude 155° to 175° W.), on board the New Bedford whaling barques Cleone, Roscoe, and Helen Snow, for 466 days in the summers and autumns of the years 1859 to 1861, and 1864 to 1870, both inclusive; also by Anthon Schonborn on board the ship Vincennes, under direction of Commander John Rogers, for five days in the summer of 1855, while engaged in the second Japan Expedition.

At sea (longitude 50° to 110° W.), by John Ross for 53 days in the summer and autumn of 1818; by Parry for 101 days in the summers and autumns of 1819, 1820, 1824, and 1825; by Snow for 31 days in the summer and autumn of 1850; by Penny for 101 days in the springs and summers of 1850, 1851, and (?) 1852; by Kane for 305 days in the years 1850 to 1853 inclusive; by Kellet and McClure for 64 days in the summer of 1853; and by McClintock for 159 days in the years 1857, 1858, and 1859. Total 814 days.

Assistance Harbor, Boothia Felix, by Penny from September 1st, 1850, to August 11th, 1851; all, except for the first 12 days, being made at the anchorage.

Baring's Island, by McClure in the year 1853 (?).

Dealy Island, by McDougal, on board the ship Resolute, from September 2d, 1852, to April 30th, 1854, with the exception of the month of January, 1854. From September 9th to November 12th, 1853, the ship was drifting with the ice from latitude 74° 59′ to 74° 30′, and from longitude 105° 38′ to 101° 11′ W.

Felix Harbor, Boothia Felix, under direction of John Ross from October 1st, 1829, to September 30th, 1830.

Melville Island and vicinity, by Parry from August 28th, 1819, to August 27th, 1820. For 314 days the observations were made at Winter Harbor, on the southern shore of the island; for 48 days along the southern shore, and for the remaining four days a little eastward from the island.

Port Bowen and vicinity, by Parry at Port Bowen, from September 28th, 1824, to July 19th, 1825, in Prince Regent's Inlet for 46 days, and in the neighboring seas for 24 days, to complete the year.

Port Kennedy and vicinity, by McClintock from August 19th, 1858, to August 18th, 1859, viz.: at the port from September 16th, 1858, to August 8th, 1859; in Bellot Straits, and other places within 60 miles of the port, from August 19th to September 15th, 1858, and from August 9th to 15th, 1859, and during the 16th, 17th, and 18th of August, 1859, in Prince Regent's Inlet, at distances from the port varying from 60 to 160 miles.

Sheriff's Harbor, Boothia Felix, by John Ross from October 1st, 1830, to September 30th, 1831. Victoria Harbor, Boothia Felix, by John Ross from October 1st, 1831, to March 31st, 1832.

(No. 1.) Arctic Ocean. Longitude 155° to 175° W.

Captain McClure, speaking of the possibility of effecting a passage toward the northeast, on the southeast side of the island, between it and Prince Albert's Land, in latitude 72° 50′ to 73° 13′, and longitude 115½° to 118°, says, "I considered it not practicable, except under the favorable circumstance of a continuance of southwesterly winds, which would drive the ice into Barrow Strait; but I imagine there would be but little difficulty in coming in from the N. E., from which quarter we found the winds to prevail." Again, speaking of the sea on the northwest side of the island, he says, "we have invariably remarked that there is a decidedly easterly current" (i. e. toward the east) "which impels the enormous polar floes in that course; while the lighter, influenced by the wind, is oftentimes setting in the opposite direction."

¹ As the observations from October to March inclusive cover an aggregate period of three half years, while those for the remaining months cover only two, the former are multiplied by 2 and the latter by 3, in order to equalize them, and give to those of each month their due weight in determining the resultants for the seasons and year.

I Computed from a portion of a series of observations made during an expedition in search of Sir John Franklin under the direction of Sir Francis Leopold McClintock, and presented by him to the Smithsonian Institution. The whole series was discussed at its expense by Mr. Charles A. Schott, of the U.S. Coast Survey; and, with the exception of the fractional portions of the mouth of August, the foregoing classification of the winds, and the computation of the direction of the second series of resultants, is taken from his work. For a portion of the year, observations were recorded twelve times a day, and for the remainder only six. In order, therefore, to give to the latter their due weight in determining the resultants for the different seasons and for the year, the number of observations and the corresponding number of miles is doubled.

The estimated force of the wind was indicated by Beufort's scale of numbers from 1 to 12, and from Smeaton's table, and also from Bernoulli's formula. Mr. Schott makes the corresponding velocity to be as follows:—

Force according to	Corresponding velocity	Force according to	Corresponding velocity
Beufort's notation.	in miles per hour.	Beufort's notation.	in miles per hour.
1	1	7	40
2.	4	. 8	48
3	. , 10	. 9	56
4	17	10	67
5	24	11	82
6	32	12	100

The mean velocity of any wind for any month of the year may be found by dividing the number of miles travelled by that wind in that month, as given in the second of the following tables, by the number of miles as given in the first. For full discussion see Smithsonian Contributions, Vol. XV.

(Nos. 16 and 17.) Arctic Ocean between Greenland and Finmark.

Observed at the following places, viz .:-

At sea, by Parry, for 5 days, in the year 1827; by the French Commission, for 59 days, in the years 1838, 1839, and 1840; and by the German Polar Expedition, for 50 days, in the year 1868.

Bear Island (near Spitzbergen), by Sievert Tobiesen, from August 6, 1865, to June 19, 1866.

(Nos. 20 to 27.) Arctic Siberia and the adjacent seas.

Observed at the following places, viz.:-

Arctic Ocean, longitude 20° to 40° E., by members of the French Commission, for 62 days in the summers of 1838 to 1840.

Arctic Ocean, longitude 75° to 90° E., and 130° to 170° E., by Von Wrangel in the summers of 1734 and 1737. (?)

Bear Islands (north coast of Siberia), by Von Wrangel, from March 1st, to April 27th inclusive.

Great Northern Tundra (Taimurland), by Waldemar von Middendorf, from May 26th to August 31st, 1843. The figures denote the number of hours estimated as nearly as practicable from the published report.

Korennoje Filipovskoje, under the direction of Waldemar von Middendorf, from April 25th to October 26th, 1843.

Ust Yansk, under the direction of Lieut. Anjon, by Surgeon Figurin, for 21 months, in the years 1820, 1821, and 1822, and classified by Wesselowski in his elaborate work on the Climate of Russia.

Nova Zembla, at three places: the Straits of Kara, on the S. E. Matotschkia Schar, and Shallow

Bay, on the western coast; aggregate $4\frac{1}{2}$ years—1832 to 1835.

¹ Von Wrangel experienced contrary winds when sailing northeasterly from the mouth of the Obi up to latitude 73° 18' in the summers of 1734 and 1737.

² The percentages are given for the summer and winter, and the whole number of observations for the year.

³ Von Wrangel states that near the mouth of the Kolyma river the prevailing wind is from the northwest; also that contrary winds prevented his sailing westerly from the east mouth of the Lena for 5 days in June, 1835; but miscellaneous notices of the wind, scattered through his journal, seem to indicate that, along the seas adjacent to this part of the Siberian coast, the direction is rather northeasterly.

ZONE No. 5.

LATITUDE 65° TO 70° NORTH.

The data for the study of the winds of this zone consist of observations made in the following portions of it:—

- 1st. Arctic seas of North America and Greenland, and islands in the same, for an aggregate period of more than four and a half years.
- 2d. North America, at five different stations, for an aggregate period of nearly six years.
- 3d. Greenland, at two stations on its western coast, for periods severally of five and twelve years.
- 4th. Northern and Western Iceland, at two stations, for periods severally of two and five years.
 - 5th. Atlantic Ocean, between Iceland and Norway, for thirty-three days.
- 6th. Finmark and Lapland, at nine stations, for an aggregate period of over seven years.
- 7th. Northern Sweden, at four stations, for an aggregate period of twenty-two and a half years.
- 8th. Northeastern Siberia, at two stations, at one of which observations were regularly recorded for a period of seventy-two days, and at the other we have the general result only for a period of three years.

In this zone, therefore, the observations regularly recorded, and incorporated into this work, represent, in the aggregate, a period of nearly sixty-four and a half years.

(Nos. 1 and 2.) Behring Strait and vicinity, and Northern Alaska.

Observed at the following places, viz. :-

At sea (longitude 177° E. to 163° W.), by Beechy, for 13 days, in the summer of 1827; by Rogers and Schonborn, for 23 days, in the summer of 1855; and on board the New Bedford whaling barques Cleone, Roscoe, and Helen Snow, for 457 days, in the summers and autumns of 1859 to 1861, and 1864 to 1869, both inclusive.

Port Clarence and Kolzebue Sound, by Beechy, for 136 days in the summer and autumn of 1828.

(Nos. 3 to 9.)

Northern British America.

Observed at the following places, viz. :-

Fort Anderson, by R. McFarlane, from May, 1863, to April, 1864, inclusive.

Fort Confidence, Great Bear Lake, by Richardson, from October, 1848, to April, 1849, inclusive.

Fort Franklin, Great Bear Lake, by Franklin and Richardson, from September 11th, 1825, to
May 16th, 1827, with the exception of June, 1826, and part of July and September.

Fort Hope, Repulse Bay, by Rae, from September, 1846, to August, 1847, inclusive, and during the year 1854.

Fort McPherson, by Andrew Flett, for ten months, from February to November, 1863.

Igloolik and vicinity, by Parry, from August 13th, 1822, to August 12th, 1823, viz., 317 days at Igloolik, 9 days along the northeast coast of the peninsula, 28 days in the Strait of Fury and Heckla (lat. 69° to 70°, long. 82° to 86° W.), and the remaining 11 days off the west entrance of the same.

Winter Island and vicinity, by Parry, from August 1st, 1821, to July 31st, 1822, viz., 269 days at the island, 65 days in various bays and straits within 100 miles of it, 6 days in the upper part of Hudson's Strait, and the remaining 25 days off the northeast coast of Melville Peninsula.

(Nos. 14 and 15.) Northern and Western Iceland.

Observed at the following places, viz.:-

Eyafiord, by Van Scheels, from June 1st, 1811, to May 31st, 1813. The observations were made sometimes once, sometimes twice, and sometimes thrice a day. When only one was made it is taken to represent a day in this discussion; when two, each as half a day; and when three, each as one-third of a day.

Stykkisholm, during the years 1866 to 1870 inclusive. Communicated by A. O. Thorlacius to Dr. Buchan.

(Nos. 16 to 21.) Lapland, Finmark, and the adjacent seas.

Observed at the following places, viz. :-1

Andennes, Finmark, from 1863 to 1868 inclusive.

Atlantic Ocean (long. 15° W. to 15° E.) by the French Commission, for 28 days at different times in the summers and autumns of the years 1838,1839 and 1840, and by the German Polar Expedition for 5 days in the year 1868.

Arctic Ocean (long. 30° to 40° E.) for 15 days in the summers of the aforesaid years.

Bossekop, Finmark, from August 30th, 1838, to May 16th, 1839.

Kautokeino, Finmark, for 2 days in April, and 4 in September, in the year 1839.

Kiexisvara, Lapland, for 24 days in May, 1839.

Kolare, Lapland, for 2 days in May, 1839.

Kilangi, Lapland, for 2 days in April, 1839.

Karesuando, Lapland, for 2 days in April, 1839.

Muonioniska, Lapland, for I day in April, 1839.

Tromsoe, Finmark, from July to November, inclusive, 1867. Reported to the Meteorological Institute of Norway.

(Nos. 26 and 27.)

Northeastern Siberia.

Observed at the following places, viz .:-

No. 26. Nijnii Kolimsk, by Baron Wrangel, in the years 1820, 1821, and 1822, who says that a northwest wind "blows almost without intermission," and in another place that the sea winds "always prevail."

Anadyrsk, by a member of the Russo-American Telegraph Expedition in the years 1866 and 1867. See note to Nos. 69, 70, and 71 of Zone No. 6.

No. 27. Bush's Station, by George Bush, from October 21st to December 31st, in the year 1866, as follows:-

Autumn

North 9, N. E. 2, East 15, S. E. 7, West 29, N. W. 16; calm or variable 4.

Direction of resultant N. 48° 29′ W.

Ratio of resultant to sum of winds, 31.

Number of days, 41.

North 1, N. E. 1, East 8, S. E. 2, South 1, West 16, N. W. 30.

Direction of resultant N. 52° 52′ W.

Ratio of resultant to sum of winds, 58.

ZONE No. 6.

LATITUDE 60° TO 65° NORTH.

The data for the study of the winds of this zone consist of observations made in the following portions of it, aggregating about 420 years:—

	Regio	n.				No. of stations.	Aggregate length of time.
American Continent Greenland Hudson's Strait, Baf Southwestern Icelan Norway and Sweden	fin's Bay d and F	7, and	Atlaı	atic O		9 2 5	567 days. Over $11\frac{1}{2}$ years. 19 months. 256 days. Nearly 35 years. 71\frac{1}{4} years.
European Russia Siberia	:	:				22 8	$270\frac{1}{2}$ years. Over 27 years.

(Nos. 1 to $6\frac{1}{2}$.)

Pacific Ocean and Alaska.

Observed at the following places, viz .:-

At sea (longitude 172° E. to 160° W.), by Beechy, for 21 days in the summers and autumns of the years 1826 and 1827; by Rogers and Schonborn, for 43 days in the summer of 1855; and on board the New Bedford whaling barques Cleone, Roscoe, and Helen Snow for 295 days in the springs, summers, and autumns of 1859 to 1861, and 1864 to 1870, both inclusive.

Fort St. Michaels, Alaska, by H. M. Bannister, of the Russo-American Telegraph Expedition, from October 15th, 1865, to August 31st, 1866, and communicated by him to the author.

Ikogmut (on the river Kwipack), Alaska, by Jacques Netzvetof, and communicated by C. Wesselowski to Prof. Kaemtz for insertion in the Repertorium für Meteorologie. The observations appear

ě	Nijnii Kolymsk.	Percentage of	winds in	winter:	3 years, 182	20-22.	
	N.	N. E.	\mathbf{E}_{*}	S. E.	S.	s. w.	W.

Wrangel does not give the winds for each day, but says that moderate and strong winds from this direction blew on these days, etc. From these remarks the above percentage was computed by Dr. Woeikof.

N. W.

(Nos. 1 to 61/2.) Pacific Ocean and Alaska.—Continued.

to have been made once a day, and extend (with interruptions amounting in the aggregate to 396 days) from September 13th, 1848, to July 6th, 1854.

Nulato, Alaska, by W. H. Dall, of the Russo-American Telegraph Expedition, by means of a pennant 60 feet from the ground, from December 1st, 1866, to May 26th, 1867.

Plover Bay, Alaska, on board the New Bedford whaling barque Cleone, from September 18th, 1859, to July 13th, 1860, with frequent omissions.

Unalakleet, Alaska, by F. Westdahl, of the Russo-American Telegraph Expedition, from October 19th, 1866, to January 23d, 1867.

¹ The observations at this place were recorded originally for 16 points of the compass, but were reduced to eight by Mr. Wesselowski, who distributed those from the intervening points equally between the two on either side. He also further modified the record by expressing the number of observations in parts of 10,000. As his communication does not show in what months or seasons of the year the omissions of the 396 days (as already mentioned) occurred, the column headed "number of days" is filled on the assumption that they were distributed uniformly over the entire period.

Computed from the resultants for the seasons.

(Nos. 7 to 11.) Hudson's Bay Territory.

Observed at the following places, viz.:-

Fort Enterprise, by Sir John Franklin, from September 1st, 1820, to August 31st, 1821, but published in extenso only from January 12th to May 9th, 1821.

Fort Norman, by Andrew Flett, for five months of 1862 and 1863.

Fort Rae, Great Slave Lake, by Lawrence Clarke, Jr., 1859-60; and by Mrs. Lawrence Clarke, Jr., 1861-64.

Fort Reliance, Great Slave Lake, by Capt. Back, from November 1st, 1833, till May 23d, 1834, and during part of October, 1834.

Fort Simpson, by Capt. Lefroy 18 times a day during the months of April and May (date not preserved), and by Bernard R. Ross for 17 months in the years 1859, 1861 and 1862.

 $^{^2}$ Observed from the magnetic meridian, and in computing the direction of the resultants an allowance of $30^\circ\ 30'$ is made for the variation of the needle.

(Nos. 7 to 11.) Hudson's Bay Territory.—Continued.

(Nos. 7 to 11.) Hudson's Bay Territory.—Continued.

In the published abstracts for the entire year the winds are classified merely as easterly or westerly, as follows:—

	Jan.	Feb.	March.	April.	May.	June.	July.	Aug.	Sept.	Oct.	Nov.	Dec.	Total.
Easterly Westerly	14 17	15 <u>1</u> 12 <u>1</u>	$15\frac{3}{4}$.	18 12	24 7	24 6	17½ 19½	15 15	15 15	$\begin{array}{c} 22\frac{1}{3} \\ 17\frac{2}{3} \end{array}$	18 2 11 1	$\frac{10\frac{3}{4}}{20\frac{1}{4}}$	$ \begin{array}{c c} 210\frac{1}{2} \\ 148\frac{1}{2} \end{array} $

It appears from the foregoing that the preponderance of easterly winds over westerly amounts to more than 17 per cent. of the whole. And if, with a view to obtain some tolerable approximation to the probable mean direction of the summer and autumn winds, and hence that for the entire year, we distribute each of the two foregoing classes of winds among the several easterly or westerly points, in the same ratio that they actually were distributed in the recorded observations of some month in which the general result was nearly or quite similar, we obtain the following:—

	Summer.	Autumn.	The year.
Mean direction of resultant,	S. 67° 16′ E.	N. 34° 43′ E.	N. 41° 7′ E.
Ratio of resultant to sum of winds,	.14	.20	.13

(No. 12.) Baffin's Bay and Hudson's Strait. Longitude 45° to 80° W.

Computed from observations made by John Ross for 12 days in the spring, summer, and autumn of 1818; by Parry, for 81 days in the same seasons for 1819 to 1825; by Snow, for 6 days in the summer and autumn of 1850; by Kane, for 15 days in the summers of 1850 and 1853; and by McClintock for 28 days in the spring, summer, and autumn of 1857, 1858, and 1859, as follows:—

Spring: North 14, N. N. E. 2, N. E. 1, E. N. E. 1, E. S. E. 5, S. E. 12, S. S. W. 4, W. S. W. 5, W. N. W. 1, N. W. 7, N. N. W. 18; calm 2.

Direction of resultant, N. 8° 28' W.??

Ratio of resultant to sum of winds, .32.

Number of days, 13.

Summer; North 72, N. N. E. 25, N. E. 30, East 56, S. E. 49, S. S. E. 20, South 35, S. S. W. 30, S. W. 44, W. S. W. 28, West 36, W. N. W. 15, N. W. 55, N. N. W. 36; calm 22.

Direction of resultant, N. 48° 56' W.

Ratio of resultant to sum of winds, .01.

Number of days, 93.

Autumn: North 16, N. N. E. 10, N. E. 24, E. N. E. 3, East 11, E. S. E. 4, S. E. 12, S. S. E. 3, South 11, S. S. W. 15, S. W. 6, W. S. W. 3, West 18, W. N. W. 16, N. W. 33, N. N. W. 24; calm or variable, 7.

Direction of resultant, N. 30° 10' W.?

Ratio of resultant to sum of winds, .28.

Number of days, 37.

(Nos. 13 and 14.)

Southwestern Greenland.

(Nos. 38 to 59.)

Finland.

Observed at the following places, viz.:-

Abo, at the University for 77 years, from 1749 to 1826 inclusive, by Profs. Lexe, Kalm, Hellenius, Planman, Meter, and Hällstrom.

Galiko, for 8 years, 1818 to 1825 inclusive, by Rev. Dr. Ignatius.

Helsingfors, by Hällstrom, for 12 years, 1829 to 1841; also at intervals of 20 minutes, or 72 observations per day, from December, 1852, to November, 1853, inclusive.

Hogland Lighthouse, during the year 1866, by Antzeff.

Ilmola, by Pastor Frosterus, for 9 years (1818 to 1826 inclusive).

Kajan, by Rev. Dr. Eumelius, during the years 1818 and 1819.

Kalaioki, by Rev. Dr. Frosterus, for 9 years (1818 to 1826 inclusive).

Laichela (formerly Vasa) on the shore of the Gulf of Bothnia, by Sterval, for 4 years (1751 to 1754 inclusive).

Lemo Ganula, by Dr. Freidental, for 9 years (1818 to 1826 inclusive).

Loukas, by Pastor Axwidson, for 8 years (1818 to 1825 inclusive).

Paldamo (near Kajan), by Rev. Dr. Eumelius, for 5 years (1824 to 1828 inclusive).

Storkiro, by Reimius, for 10 years (1831 to 1848).

Sweaborg, from December, 1852, to November, 1853, inclusive, and published in Kupffer's Annals, 1853.

Tammela, by Rev. Dr. Tolpo, for 14 years (1818 to 1831 inclusive).

Uleaborg, by Julin, for 12 years (1776 to 1787 inclusive); and by Rev. Dr. Frosterus, for 12 years (1818 to 1829 inclusive). A part of the latter series was made at the neighboring island, Karle.

Varo, by Dr. Vegelius, for 25 years (1800 to 1825).

Virdois, by Perden, for 7 years (1826 to 1832 inclusive).

Finland.—Continued.

(Nos. 60 to 64 (b).);

Northern Russia.

Observed at the following places, viz.:-

Archangel, for a period of $18\frac{1}{2}$ years, from about the 18th of June, 1813, to the end of 1831.

Beresov, 3 years, 1870 to 1872, by Soldatkow and N. Koschewnikow.

Kem, by Kosloff during the years 1866, 1867, 1868 and 1871.

Petrozavodsk, during the years 1840, 1841, 1844 and 1845, and published in the Siberian Times, whence they were copied, and the computations made by Wesselowski.

Ustsysolsk, District of Wologda, 8 years, 1855 to 1862, by Dr. Drschewezki.

Yarensk, by Petropopow, for 11 years, 1836 to 1848.

¹ The work of Wesselowski contains two series of results for this place, from substantially the same data. The observations for the first, which were recorded in old style for a period of 18 years from 1814 to 1831, inclusive, he quotes from the Memoirs of the Imperial Academy of Science of St. Petersburgh. The second is computed from the same series, changed into new style, with the observations for the latter half of 1813 added. As the results of the two series differ somewhat, both are here given; and also another line is added giving the results for the entire latter period, computed by the author from the original observations, and published in his former work on the Winds of the Northern Hemisphere.

¹ With the exception of the last four columns, this table is transcribed from the work of Wesselowski, in which no account is taken of calms. If we assume their relative number for the several months to have been the same as in the year September, 1837, to August, 1838, inclusive, given in the author's former work, the numbers in the thirteenth column will be modified so as to read as follows, viz., January 55, February 32, March 19½, April 26, May 15, June 08½, July 07½, August 11, September 10½, October 25, November 54½, December 56, Spring 20, Summer 05½, Autumn 29, Winter 47½, the year 24.

² Dr. Kennan ascribes the monsoon character of the winds "to the influence of the Okotak Sea, whose open

2 Dr. Kennan ascribes the monsoon character of the winds "to the influence of the Okotak Sea, whose open waters are warmer than the land in the winter, and colder in the summer." He remarks that "the best point probably for observation of the wind is Anadyrsk (lat. 65° 30', long. 166° 45') as it is less influenced there by local peculiarities, such as the trend of the sea-coast, and the position of mountains and water, than it is in any other of the Siberian settlements with which I (he) am acquainted." It is much to be regretted that the series of observations made there by a member of the party, for several months, appears to be lost.

ZONE No. 7.

LATITUDE 55° TO 60° NORTH.

The data for the study of the winds of this zone consist of observations made at 188 different places on land for an aggregate period of over 1082 years, and for 5218 days, or over 14 years, at sea, distributed as follows:—

	W	here o	bserved			No. of stations.	Aggregate length of time.
Pacific Ocean							4787 days, over 13 years.
America .						10	Nearly 33 years.
Atlantic Ocean							431 days, over 1 year.
British Isles						103	Over 400 years.
Norway, Sweder		Den	mark			34	Over 310 years.
European Russi	a.					30	Over 257 years.
Siberia .			- 1			12	Over 83 years.

(Nos. 1 to 9.) Pacific Ocean. Longitude 170° E.

From observations for an aggregate period of over 13 years, collected and classified from the logs of numerous sailing vessels, chiefly at the United States Naval Observatory, under the direction of Capt. M. F. MAURY, Superintendent.

the different months are given as follows, viz.: January S. 60° 30′ W., February N. 72° 42′ W., March S. 63° 42′ W., April N. 86° 6′ W., May N. 24° 12′ E., June S. 52° 36′ W., July S. 50° 0′ W., August S. 67° 18′ W., September S. 63° 54′ W., October S. 57° 12′ W., November S. 30° 42′ W., December S. 62° 42′ W.

(No. 50.)

North Sea.

Computed from observations collected and classified, from the logs of different sailing vessels, at the United States Naval Observatory, under the direction of Capt. M. F. Maury, Superintendent, as follows, viz.:—

Summer: N. N. E. 11, N. E. 17, East 4, E. S. E. 10, S. E. 4, S. S. E. 2, South 13, S. S. W. 6, S. W. 28, W. S. W. 2, West 5, W. N. W. 13, N. W. 3, N. N. W. 3; calm or variable, 3.

Direction of resultant, S. 35° 38' W.(??)

Ratio of resultant to sum of winds, .15.

Number of days, 26.

Autumn: North 2, N. N. E. 2, N. E. 2, E. N. E. 15, East 7, E. S. E. 9, S. E. 6, S. S. E. 4, South 10, S. S. W. 17, S. W. 19, W. S. W. 3, West 6, W. N. W. 2, N. W. 4, N. N. W. 2; calm or variable, 34.

Direction of resultant, S. 3° 22' E.(?)

Ratio of resultant to sum of winds, .24.

Number of days, 40.

(Nos. 50(a) to 56.)

Southern Norway.

Observed at the following places, viz. :-

Christiana, at the Observatory from April, 1837, to December, 1863, inclusive, and 1867.

Lindesnes, for 6 years, 1863 to 1868, inclusive.

Lister, for 6 years, 1863 to 1868, inclusive.

Mandal, by Hansen, for 7 years, 1861 to 1867, inclusive.

Sandosund, by Olsen, for 7 years, 1861 to 1867, inclusive.

Skudesnes, by Christensen, Storhoug, and Egeland, for 7 years, 1861 to 1867.

Spydberg, during the years 1784 and 1785. The author is in doubt in regard to the geographical position of this place.

Carlstadt, Gronberg, Goteburg, Halmstad, Lund, and Wenersborg.
 Askersund, Carlshamn, Kalmar, Linkoping, Nykoping, Orebro, Skara, Stockholm, Upsal, Westeras, Westervik, and Wexio.

Russia.

Observed at the following places, viz. :-

Avandus, on the estate of Admiral Von Lütke, and under his direction, from November, 1857, to October, 1860, inclusive.

Balachna, by Mr. Borissoff, during the years 1857, 1865 and 1866.

Baltischport, during the year 1857.

Cronstadt, during December, 1852, nine months of 1853, and nine months of 1857.

Dorpat, during the years 1842, 1855, 1856, 1857 (except December) and 1859.

Fellin, for 22 years, 1824 to 1846, quoted by Wesselowski from the correspondence of the Society of Natural Sciences at Riga.

Glasof, by Mr. Mischkin, during the years 1865 and 1866.

Gorbatov, during the year 1857.

Gryasovez, during the years 1835 and 1839, quoted by Wesselowski from a work of Danilewski on the climate of the Vologdian regions.

Ichak, during the years 1853 and 1857, by Mr. Gromoff.

Kazan, for one year (date not preserved).

Kosmodemiansk, by Mr. Gromoff, during the years 1865 and 1866.

Kostroma, during the year 1857.

Libau, by Mr. Lesseff, from December, 1864, to November, 1865, inclusive.

Mitau, during the year 1853.

Moscow. Three series of observations are given for this place. The first was made by Perwoschtschikof for 20 years, from 1810 to 1812, and from 1820 to 1836, both inclusive; but Wesselowski, from whose work the series is transcribed, expresses doubts as to the reliability of the results. The second series was made by Spasski for five years, from October, 1839, to September, 1844, inclusive, and published in his work on the climate of Moscow. The third series embraces also a period of five years, neither the date of which nor the name of the observer is preserved.

Nijnii Novogorod, by A. S. Saveliew, at the Gymnasium, for twelve years, 1837 to 1848 inclusive. Nijnii Taguilsk. The first series, embracing a period of nine years, 1843 to 1851, inclusive, was originally recorded for sixteen points of the compass, but was reduced to eight points by Wesselowski, from whose work the series is transcribed, by distributing those for intermediate points equally between the two adjacent ones, i. e., by putting $\frac{1}{2}$ N. N. W. + N. + N. N. E. = North, etc. The second series is added chiefly for the purpose of showing the relative number of calms, as indicated by the observations for the seasons of the year 1853, and for the years 1848 and 1849 in the aggregate.

Novogorod, by Lesnewski, during the years 1852, 1853, 1854, 1855 and 1857.

Pakerort Lighthouse, during the year 1866, by Orloff.

Reval, by Sheferdeker, for 33 years, 1815 to 1848. For the first seven years they were made on the estates of the parish of St. Catherine, and for the remaining years within the city of Reval. By combining with the foregoing the observations for the year 1853, and nine months of 1857, and assuming that the proportion of calms for the former series, where no record of them is given by Wesselowski, from whose work the series is copied, was the same relatively as in the two latter years, of which we have the record, a second series of results for the seasons and year has been obtained.

Riga, by Dr. Leters, for a period of seven years, from 1842 to 1848, inclusive. The second series is obtained by combining with the foregoing the observations for the year 1853, and three months of 1850.

St. Petersburg. The first series embraces observations for a period of 23 years, viz., for 13 years (1822 to 1834 inclusive), by Wischnewski, at 7 A. M., 2 P. M. and 9 P. M.; and for 10 years (1841 to 1850 inclusive), hourly at the Observatory of the Institute of Mining Engineers. The second series gives the results for the several hours of the day for the ten years last mentioned, and includes calms, which are omitted in the first series. The third series gives the results for the years 1830, 1831 and 1832, and from July, 1835, to June, 1837, inclusive, computed from hourly observations, and includes calms. The fourth series embraces the third together with the year 1857. To these are appended results for the years 1783 and 1818, and for 20 years of unknown date; also a table

Russia .- Continued.

prepared by Mr. Wesselowski to show how the mean direction of the wind at 7 o'clock A.M., 2 P.M. and 9 P. M. differs from that for the entire 24 hours of the day in the different months of the year. Slobodsk, during the years 1857, 1865 and 1866, by Mr. Koroboff.

Syevernaja Utschebnaja-Ferma (Northern Agricultural School), for a period of nine years, 1847 to 1855 inclusive.

Totma, from May, 1848, to December, 1850, inclusive, quoted by Wesselowski from Danilewski, as above.

Tschermoski, District of Perm, 1865, 1866 and 1867, by Dr. Goworliwi.

Viatka, during the year 1857.

Vladimir, by Dubenski, for a period of nineteen years, from 1832 to 1850 inclusive, quoted by Wesselowski.

Vologda. The first series embraces a period of $3\frac{1}{2}$ years, 1844 to 1847, quoted by Wesselowski from Danilewski. The second for the summer and autumn of 1850 is added for the purpose of showing the relative number of calms, of which there is no record in the first series. The third is computed from the first and second, due allowance being made for calms.

Zlatouste. The first series embraces a period of four years, from December, 1849, to November, 1853, inclusive. The second is derived from observations made in the years 1837, 1850, 1853 and 1857, and includes calms. The third is a combination of the other two, due allowance being made for calms.

¹ Giving to the observations at each place a weight proportional to the length of time covered by them respectively.
² Transcribed from Wesselowski, except the last four columns. His ratios of resultants have been modified by making a due allowance for calms, as indicated by the observations in 1853 and 1857.
³ Computed from the resultants for the seasons.

(Nos. 127 to 136.)

Siberia.

Observed at the following places, viz. :-

Ajan, from September, 1847, to August, 1849, inclusive.

Bogoslowsk, during the years 1842 and 1857, and from December, 1849, to December, 1853, inclusive. The first series, except the last four columns, is transcribed from Wesselowski's work on the Climate of Russia, in which no account is taken of calms; and the second is inserted chiefly for the purpose of showing their relative proportion in the different seasons of the year. The third is a combination of the other two, due allowance being made for calms in the first.

Catharinenburg, during the years 1836, 1837, 1841 to 1850 inclusive, 1853 and 1857. The first series, except the last four columns, and the second entire are transcribed from the aforesaid work of Wesselowski, and the third and fourth correspond with the second and third in the previous number (Bogoslowsk).

Galanowsk, by Rev. Alexei Emeljanow, from September, 1857, to August, 1858, inclusive.

Ichim, from December, 1852, to November, 1853, inclusive, and 1857.

Jenisseisk, from May to December, 1871, inclusive, by Marx.

Kourgan, at the district school for ten years, 1842 to 1851 inclusive. The observations for the year 1853 are added to show the relative number of calms.

Krasnojarsk, during the month of May, 1868, and from June, 1870, to February, 1871, inclusive. Nasimowo, by Middendorf, from June 14, 1843, to May 28, 1844, and from August 11 to September 29, 1844.

Tara, from 1832 to 1841 inclusive, 10 years.

Tobolsk, for a period of ten years, date not preserved; also from 1852 to 1861 inclusive; also (in the Addendum) from January, 1870, to May, 1872, by Slauty.

Tomsk, from December, 1852, to November, 1853, inclusive.

Werch Pelymsk, during the year 1871 (old style), by Djukow.

ZONE No. S.

LATITUDE 50° TO 55° NORTH.

The data for the study of the winds of this zone consist of observations made at 218 different places on land, for an aggregate period of not less than 1174 years, probably over 1200 years, and for nearly 30 years at sea, viz., 9327 days on the Pacific Ocean, and 1533 on the Atlantic. The places on land are distributed as follows:—

Where observed.	No. of stations.	Aggregate length of time.
Aleutian Islands, America, British Isles, Continental Europe, Siberia,	1 6 108 94 9	14 years. 10¼ years. 345¼ years. Not less than 753 years, and probably over 800. Over 52 years.

(No. 1.) Aleutian Islands.

Computed from observations made at Iluluk, from the year 1825 to 1834 inclusive (old style), except the months of May, June, July, August and September, 1827, the last half of 1829, and 160 observations in the first half; and published in the Report of the United States Coast Survey for 1867.

(Nos. 26 to 48.)

Ireland south of latitude 55°.

Observed at the following places, viz .:-

Armagh, at the Coast-guard Observatory, during the year 1851.

Athu. by Houghton, during the year 1851.

Ballina, at the Ordnance Survey Office, from May to September inclusive, in the year 1838.

Bencorr, by James Crean and James Glaisher, from July 18 to August 31, 1830.

Cahirciven, at the Coast-guard Station, in the year 1851.

Castletownshend, at the Coast-guard Station, in the year 1851.

Cork, at the Barracks, in connection with the Ordnance Survey, from June, 1840, to October, 1841, inclusive, and during the years 1857 to 1867 inclusive.

Courtown, at the Coast-guard Station, in the year 1851.

Cuilcagh, from June 17 to September 13, 1828.

Donagadee, at the Coast-guard Station during the year 1851.

Divis, from September 1 to November 13, 1825.

Dublin. There are three series of observations from this city, one made at the Coast-guard Observatory during the year 1851, and another at the Ordnance Survey Office, Phænix Park, for 22 years, from 1831 to 1852 inclusive. The latter were originally recorded for 16 points of the compass, but were reduced, for publication, to eight points, in the same manner as at Nijnii Taguilsk (Zone 7, No. 126). They were also reduced so as to be expressed in parts of 100 (or parts of 1000, by removing the decimal point). Beside the record of the number of observations, showing the relative frequency of the different winds, Whewell's anemometer was used after the year 1839, and Lind's was added in 1845. The third series extends from the year 1857 to 1867 inclusive, at 9\(\frac{1}{2} \) o'clock A. M.

Dunmore, at the Coast-guard Station, during the year 1851.

Forth Mountain, from October 17 to November 2, 1829.

Hill of Howth, from November 29 to December 27, 1829.

Keeper, from September 19 to December 27, 1830, and from June 1 to July 9, 1831.

Killough, at the Lighthouse during the year 1851.

Killybegs, at the Lighthouse during the year 1851.

Kilrush, at the Ordnance Survey Office, from April, 1840, to December, 1841.

Kippure, from January 11 to July 16, 1829.

Knockanaffrin, from August 12 to October 5, 1829.

Limerick, at the Ordnance Survey Office, from 1839 to 1842 inclusive.

Markree, at the Coast-guard Observatory, in the year 1851

Milltown, during the years 1867 and 1868.

Nephin, from October 6 to November 2, 1828.

Portarlington, by Dr. Hanlon, during the year 1851.

Sawel, from September 8 to 19, 1827.

Slieve Donard, from August 27 to November 19, 1826.

Slieve League, From November 23, 1827, to January 5, 1828.

Tara Hill, from November 8 to 20, 1829.

Westport, at the Lighthouse, during the year 1851.

England.

Observed at the following places, viz. :-

Alderly Rectory, during the year 1821.

Aldershot Camp, during the years 1867 and 1868.

Allenheads, during the years 1867 and 1868.

Rarnstable, during the years 1867 and 1868.

Bath, during the years 1867 and 1868.

Boston, during December, 1854, and the years 1855, 1856, 1867 and 1868.

Bournemouth, during the year 1867.

Bristol, during the years 1777 and 1778.

Bushy Heath, by Col. Beaufroy, during the years 1818 to 1822 inclusive, 1824 and 1825.

Cambridge, first six months of the year 1857

Camden Town, during the year 1868.

Cardington, during the years 1867 and 1868.

Carlisle, during the years 1835, 1867 and 1868.

Cheltenham, during the year 1837, by Moss.

Chiswick, by W. B. Booth, during the years 1827 and 1856.

Clifton, during the years 1853 to 1862 inclusive.

Cockermouth, during the years 1867 and 1868.

Delphen, during one year-date not preserved.

Derby, during the years 1812, 1813, 1867 and 1868.

Devonport, during the years 1841 and 1842.

Eastbourne, during the years 1867 and 1868.

Eccles, during the years 1867 and 1868.

Epping, by T. Squire, during the year 1826.

Exeter, during the months of October and November, 1857.

Gloucester, during the years 1867 and 1868.

Gosport, by W. Burney, during the years 1816 to 1820, and 1825 to 1829, both inclusive.

Grantham, during the year 1868.

Greenwich (Observatory), during the years 1800 to 1808 inclusive, 1841, 1842, from December, 1854, to November, 1855, inclusive, and during the years 1867 and 1868.

Halifax, during the years 1867 and 1868.

Hawarden, during the years 1867 and 1868.

Helston, during the years 1822 and 1825, by M. P. Moyle; also during the years 1857 to 1868 inclusive.

High Wycombe, during one year-date not preserved.

Holkham, during the years 1867 and 1868.

Hull, by William Lawton, during the years 1849 to 1852 inclusive.

Kendal, by Marshall, during the year 1828, and five years whose date is not preserved.

Keswick, during one year-date not preserved.

Kingsley Parsonage, during the year 1867.

Lampeter, during the year 1868.

Lancaster, by John Heaton, during the years 1816, 1817, and 1819 to 1821 inclusive.

Leeds, during the years 1867 and 1868.

Liverpool, by Abraham, from 1828 to 1834 inclusive; also by some observer whose name does not appear, from 1852 to 1855 inclusive.

London, by Howard, during the years 1806 to 1818 inclusive.

Manchester, by Thomas Hanson, during the years 1819, 1820 and 1821; also by observers whose names do not appear, during the year 1801, and three years whose date is not preserved.

Mansfield Woodhouse, during a period of ten years, whose date is not preserved.

Marlborough College, during the years 1867 and 1868.

New Malton, by J. Stockton, during the years 1819 to 1822 inclusive, and 1825.

North Shields, during the years 1867 and 1868.

England.—Continued.

Nottingham, during the months of January to June, 1811, and July to November, 1857, both inclusive, and during the year 1868.

Norwich, during the year 1868.

Osborne, during the years 1867 and 1868.

Otley, during the years 1867 and 1868.

Oxford, during the years 1828 to 1832 inclusive, 1854, 1867 and 1868.

*Penzance, by E. C. Giddy, during the years 1807 to 1827 inclusive.

Ripon, during the years 1867 and 1868.

Royston, during the years 1867 and 1868.

Sidmouth, from September, 1811, to December, 1813, inclusive, and during the years 1867 and 1868.

Silloth, during the years 1867 and 1868.

Southwick, during a period of eleven years—date not preserved.

Stonyhurst, during the years 1867 and 1868.

Stratford, by R. Howard, from October, 1822, to May, 1826, inclusive.

Strathfield Turgiss, during the year 1868.

Streatly Vicarage, during the year 1868.

Sturbington, from December, 1843, to November, 1844, inclusive.

Thetford, during the year 1837, by Bailey.

Truro, during the years 1867 and 1868.

Tunbridge Wells, during the year 1868.

Wakefield, during the year 1867.

Weybridge Heath, during the year 1868.

Wilton, during the years 1867 and 1868.

Wisbech, during the years 1867 and 1868.

Worthing, during the years 1867 and 1868.

York, during the year 1868.

In the published report of these observations the direction of the resultant for each month was given, but not its magnitude, and in computing from them the resultants for the seasons, as here given, the magnitudes were assumed to be equal.

2 Computed from the resultants for the seasons.

3 For the first six years only.

(Nos. 144 to 160.)

(Nos. 161 to 177.)

Northwestern Germany.

Computed from observations made at the following places, viz.:-

Bremen, by Dr. Heineken, during the years 1829 to 1858 inclusive—as quoted by Dr. Prestel, from a publication of them, by Dr. Hæpke.

Brocken (mountain), Saxony, by Dr. Nehse, during the years 1836 to 1845 inclusive. (Transactions of the Geographical Society of Berlin.)

Cottbus, Prussia, during the months of October and December, 1855, and January and February, 1856.

Cuxhaven. The date of the observations at this place is not preserved, and it is uncertain whether they embrace a period of twenty years or of only ten years.

Dusseldorf, Prussia, during the year 1783.

Emden, Hanover, during a period of 30 years, by Dr. Prestel-date not preserved.

Gotha, by von Loof, during the year 1846. (Monthly Transactions Geographical Society of Berlin.) Gottingen, Hanover, during the year 1783.

(Nos. 161 to 177.) Northwestern Germany.—Continued.

Hamburg, for a period of 30 years, as published by Buck, in his "Climate and Weather of Hamburg," and for the succeeding 18 years, by Dr. V. G. Zimmerman. The dates are not given by Dr. Prestel, from whom these observations are quoted.

Hanau, Hesse-Cassel, during the months of February to June inclusive, 1857.

Luneburg, Hanover. The remarks for Cuxhaven apply also to this place throughout.

Mulhausen, from December, 1854, to November, 1857, inclusive.

Munster, Prussia, published by Dr. Prestel, who does not give the length; of the period of observation nor the date.

Norderney, Hanover, from April, 1858, to December, 1862, inclusive.

Paderborn, Prussia, during 21 months, in the years 1854 to 1857 inclusive.

Stone Lighthouse.1 Nothing but the direction of the resultant is given in the report from this place.

(Nos. 181 to 198.)

Northern Germany.

Observed at the following places, viz. :--

Alstedt, Prussia, during the years 1825, 1826 and 1827.

Aschersleben, Prussia, Dr. Mahlmann, from whom we quote, gives the resultant for this place, but not the data from which it was computed.

Berlin, Prussia, during the years 1769 to 1779, from December, 1854, to November, 1855, from December, 1856, to November, 1857, all inclusive; also during two periods without date, one of 17 years, reported by the British Association for the Advancement of Science, and the other of 25 years.

Dessau, during the month of March, 1855.

Dresden, Saxony, from December, 1854, to November, 1857, inclusive.

Erfurth, Saxe-Weimar, during the years 1781 to 1784 inclusive, and also during a period of five years whose date does not appear.

Frankenheim, Bavaria, during the years 1825 and 1826.

Hof, Bavaria, during the year 1841.

Ilmenau, Saxe-Weimar, during the years 1823 to 1827 inclusive.

Jena, Saxe-Weimar, during the years 1823 to 1827, and 1833 to 1835, both inclusive.

Leipsic, Saxony, from December, 1854, to November, 1857, inclusive (except July, 1856).

Putbus, Prussia, from December, 1854, to November, 1857, inclusive.

Schöndorf, Saxony, during the years 1823 to 1826 inclusive.

Stettin, from 1848 to 1867, twenty years; published annually.

Strehla, Saxony, during 19 months of the years 1854 to 1857 inclusive.

Weimar, Saxe-Weimar, during the years 1823, 1824, 1825 and 1827.

(Nos. 209 to 218.) Poland, Silesia, and Northeastern Prussia.

Observed at the following places, viz.:-

Braunsberg, Prussia, during the year 1836.

Breslau, Silesia, from October, 1855, to February, 1856, inclusive.

Cracow, Poland, during the years 1826 to 1851 inclusive, 1855 and 1857.

Dantzic, Prussia, during the years 1813 to 1827.

Konigsberg, Prussia, by Prof. E. Luther, as quoted by Dr. Prestel, who does not give the date nor the length of time over which the observations extend; also during the year 1855.

Pillau, Prussia, during the years 1816 to 1833 inclusive.

Posen, Poland, during the years 1848 to 1865 inclusive, and published in a memoir of Dr. A. Magener on the Climate of Posen.

Sagan, Silesia, during the years 1781, 1782 and 1783, and also during a period of five years, whose date is not preserved.

Warsaw, during the months of November, 1855, February, November and December, 1856, and January, 1857.

Russia.

Observed at the following places, viz .:-

Brestlitowsk, from December, 1852, to April, 1863, inclusive.

District of Elnia, by Marks, for a period of eight years (1845 to 1853), and published weekly in the Journal of Trade.

Gorki, by Schmidt, during the years 1844 to 1854 inclusive.

Kalouga, from December, 1852, to November, 1853, inclusive, and 1857.

Kiev, by Kobisov, at the Botanical School, during the years 1854 and 1855.

Koursk, during the years 1840 to 1846 inclusive—resultants computed by Spasski.

Krutez, by A. Nikolaiki, during the years 1846 to 1850 inclusive.

Minsk, in the year 1850, from June to October inclusive.

Orel, by Prof. Basilius Petrov, during the years 1838 to 1845 inclusive.

Orenburg, during the years 1848 to 1867 inclusive, published in the Imperial Russian Geographical Society's publications, calculation made by Ovodof.

Pensa, during the year 1857; also from January, 1862, to November, 1870, inclusive, with the omission of the seven months, April to October, 1867, by Dr. Holmskij.

Samara, during the years 1859 to 1869 inclusive, by Dr. Ukke.

Samarskaja Utschebnaja Ferma (agricultural school of Samara), during the years 1848 to 1854 inclusive.

Saratov, during the year 1836, and ten years whose date is not preserved.

Smolensk, from June to November inclusive, in the year 1850.

Tambof, by Dr. Reng, during the years 1825 to 1836 inclusive.

Tula, by Dr. Moritz, during the years 1846 and 1847.

Ufa, by Bosse, during the years 1835 to 1849 inclusive.

Uralsk, during the year 1853, and by H. Kahnikoff, from September 13, 1839, to November 12, 1841.

Voronesch, from January, 1852, to April, 1854, inclusive, and published in the work of Taratschkov, on the Climate of Voronesch.

Wilna, from April, 1770, to March, 1771, inclusive.

Woltschansk, from January to May, and from September to November, both inclusive, in the year 1853, 1857 entire.

¹ Transcribed from Wesselowski.
² The ratios of the resultants are those of Wesselowski, modified by making allowance for calms.
³ If to the observations here given we add a series taken from June to November, inclusive, in the year 1850, the resultant for summer becomes N. 78° 47′ W..17, for autumn S. 23° 30′ W..15, and for the year S. 60°48′W..11.
¹ Using only one-third of the numbers for Gorki (No. 222) in order to give them only their proper weight; annual resultant combined by plotting.
⁵ Computed from the resultants for the seasons.

Nos. 237 to 238, resultant combined by plotting.
 Transcribed from Wesselowski, except the last four columns.
 The annual resultant for the years preceding 1840 is, according to Kahnikoff, N. 15° 25' W. .107, and if we combine the two we obtain for an aggregate resultant N. 10° 32' E. .085.

(Nos. 241 to 248.)

Southern Siberia.

Observed at the following places, viz .:-

Akmollinsk, from December, 1870, to November, 1871, inclusive, by Captain Lasarew.

Barnaule, from December, 1849, to December 1853, inclusive, and during the years 1838 and 1857.

Douai Lighthouse (Dui) Saghalien Island, during the year 1866, by Gousseff; also from October, 1863, to December, 1865, inclusive; observer's name not known.

Irkutsk, during the years 1830 to 1844 inclusive.

Mines of Nertschinsk, 300 kilometres Southeast of the city of Nertschinsk, hourly from December, 1849, to November, 1853, inclusive, and during the years 1842 and 1857. In the first of the three series, given in the table below, calms were not included, and the third is a combination of the first and second, an allowance being made for calms in the first in the same proportion as shown in the second. Also (in the Addendum at the end of this zone) during the years 1870, 1871, and 1872, by Torbolof and Derbin.

(Nos. 241 to 248.) Southern Siberia.—Continued.

Nikolaievsk, mouth of the Amoor, during the years 1859 to 1864 inclusive, and 1866, by Degtinsky. Also in the Addendum, the year 1871, by Kudrin.

Omsk, from January, 1870, to May, 1872, by Znamenski; see Addendum.

Petropaulowski, Kamtschatka, during the years 1848, 1849 and 1850, and published in the Journal of the Hydrographic Department.

Semipalatinsk, during the years 1863 to 1866 inclusive, by Abramoff.

Udskoi Ostrog, by Middendorf, from September, 1844, to September 12, 1845, inclusive.

ZONE No. 9.

LATITUDE 45° TO 50° NORTH.

The data for the study of the winds of this zone consist of observations made at 342 permanent stations on land, where the observations were regularly recorded, or during journeys and travels, where, for the most part, only a transient sojourn was made at any one place, for an aggregate period of over 1696 years; and for about 17 years at sea. The distribution is as follows:—

Where observed.	No. of stations.	Aggregate length of time.
Pacific Ocean	61 43 231 71	3109 days. Over 202 years. Nearly 200 years. 3070 days. 1246½ years. Nearly 35 years, besides general descriptions of the winds observed during journeys, travels, etc., for an aggregate period of perhaps not less than twenty years more.

(Nos. 1 to 11.) Pacific Ocean, east of longitude 180°.

Computed from observations for an aggregate period of six years, collected and classified, from the logs of numerous sailing vessels, at the United States Naval Observatory, under the direction of Capt. M. F. Maury, Superintendent.

(Nos. 52 and 53.)

Northwestern Wisconsin.

Observed at the following places, viz .:-

Ashland, Bay City or Whittlesey, by Edwin Ellis, for an aggregate period of 52 months, in the years 1856 to 1861 inclusive.

Bayfield, by H. J. Nourse, for an aggregate period of 22 months, in the years 1867, 1868 and 1869.

Odanah, by Edwin Ellis, for an aggregate period of 34 months, in the years 1861 to 1866 inclusive.

Superior, by W. H. Newton, L. and R. Washington, C. Loring, Jr., Wm. Mann, G. R. Stuntz, and E. B. Bly, for an aggregate period of nearly five years in the years 1855, 1856 and 1860 to 1863 inclusive.

Middle France.

Observed at the following places, viz .:-

Ahun, by Midre and Aristide Charière, during the years 1842 to 1865 inclusive.

Angers, by Meniere, during the years 1852, 1853, 1854; and from 1780 to 1790 inclusive, name of observer not preserved.

Arbresle, by Romand, during the years 1860 to 1865 inclusive.

Beaujeu, by Chinard, during the years 1860 to 1865 inclusive.

Besancon, by Jannot, during the years 1863 to 1865 inclusive.

Blois, by Blondin, during the years 1859 to 1861 inclusive.

Bourbonne, by Poutot, during the year 1863.

Bourg, by Jarrin, during the years 1853, 1854, and 1863 to 1865 inclusive.

Brest, by Belleville, during the year 1859.

(Nos. 98 to 165.) Middle France.—Continued.

Cercie, by Berthier, during the years 1860 to 1865 inclusive.

Chalons, by Thevenin, during the year 1864.

Cherbourg, by - during one year; date not preserved.

Clermont Ferrand, by Lecoq, during the years 1850, 1851 and 1813.

Clermont Oise, by Dr Rottec, during the years 1853 to 1860 inclusive.

Courçon, by Vincent, during the years 1851 and 1852.

Cublize, by Forneaux, during the years 1860 to 1865 inclusive.

Denainvilliers, during the years 1748 to 1778 inclusive.

Dijon, by Perrey, during the years 1845 to 1853 inclusive, and 1859.

Dole, by Domin, during the years 1863, 1864 and 1865

Doulevant, by Pissof, during the year 1859.

Duerne, by Gorges, during the years 1860 to 1865 inclusive.

Du Puy, by de Doue, during the years 1849 to 1853 inclusive.

Fecamp, by Marchand, during the years 1853 to 1859.

Fort-de-Joux, by Bassand, during the years 1863, 1864 and 1865.

Givers, by Laroche and others, during the years 1860 to 1865

Goersdoff, by l'Abbe Muller, during the years 1849 to 1855 inclusive, and 1859.

Gray, by Fourton, during the years 1863, 1864 and 1865.

Ichtratzheim, by l'Abbe Muller, during the years 1860, 1862 and 1863.

La Chapelle, by Racine and Nell de Breante, during the year 1847.

La Fleche, by de Sainthillier, during the year 1852.

La Saulsaie, by F. Pourain, during the years 1850 to 1857 inclusive.

Lons-le-Saulnier, by Bauquerre, during the years 1863, 1864 and 1865.

Lyons, by Drian, during the years 1863 to 1865 inclusive.

Metz, by Schuster, during the year 1847.

Monsol, by Forest, during six months in the year 1865.

Montbeliard, by Queney, during the years 1863, 1864 and 1865.

Montmorenci, during the years 1768 to 1782 inclusive.

Nancy, during the years 1775 to 1780 inclusive.

Nantes, by F. Huette, during the years 1854 to 1860 inclusive.

Nemours, by Dr. Goupil, during the year 1852.

Paris, at the Observatory, during the years 1806 to 1845 inclusive.

Rouen, by Preisser, during the years 1845, 1846, 1848, 1849, 1853, 1854, 1856 and 1857.

Rousses, by Simon, during the years 1862 to 1865 inclusive.

St. Foy, by Broalier, during the years 1860 to 1865 inclusive.

St. Laurent d'Oingt, by Chabert, during the years 1860 to 1865 inclusive.

St. Lo, by Lamarck, during the years 1844, 1845 and 1846.

St. Nizier, by Chassagne, during the years 1860 to 1865.

St. Rambert, by Sauvanau, during the years 1838 to 1843 inclusive.

Strassburg, during a period of twenty years; date not preserved.

Syam, by Thorel, during the years 1845 to 1849 inclusive.

Tarare, by Desroches, during the years 1860 to 1866 inclusive.

Valognes, by Benoist, during the year 1847.

Vendome, by Renou, during the years 1859, 1862 and 1863.

Verdun, by Dubois, during the year 1865.

Versailles, by Berigny, during the years 1847 to 1855 inclusive, 1857, 1858, 1862 to 1865 inclusive, and 1867.

Vesoul, by Mellasseau, during the years 1863, 1864 and 1865.

(Nos. 274 to 304.)

Luxemburg and Southern Germany.

Observed at the following places, viz .:--

Anspach, Bavaria, during the year 1843.

Bamberg, Bavaria, from December, 1854, to November, 1857, inclusive.

Burglengenfeld, Bavaria, during the year 1843.

Carlsruhe, Baden, during the years 1819, 1834 and 1835.

Giengen, Bavaria, during the year 1841.

Giengen on the Brenz, Bavaria (or Wurtemberg?) during the year 1841.

Gunzenhausen, Bavaria, during the year 1843.

Hohenpeissenberg, Bavaria. (See No. 312.)

Ingolstadt, Bavaria, during the year 1781.

Issny, Wurtemberg, during the year 1841.

Ittendorf, Bavaria. (See No. 311.)

Luxemburg, during the years 1855, 1856 and 1857.

Manheim, Baden, during the years 1781, 1784 and 1785, and from December, 1854, to November, 1855, inclusive; also, for a period of years whose date is not preserved.

Mergentheim, Baden, during the year 1841.

Munich, Bavaria, during the years 1781, 1783 to 1785, 1825 to 1837, and 1843 to 1857, all inclusive.

Neustadt, Bavaria, during the first nine months of 1842 (or 1843?).

Peissenberg, Bavaria, during the years 1781, 1783, 1784 and 1785.

Ratisbon (Regensburg), Bavaria, during the years 1783, 1784, 1785 and 1788.

Schussenreid, Wurtemberg, during the year 1841.

St. Andex, Bavaria, during the years 1781 to 1785 inclusive.

Southern Germany.—Continued. (Nos. 274 to 304.)

Stuttgard, Wurtemberg, for a period of one year; date not preserved.

Tegern See, Bavaria, during the years 1781, 1783, 1784 and 1785.

Treves (Trier), Prussia, during the years 1855, 1856 and 1857.

Tutlingen, Wurtemberg, during the year 1841.

Uffenheim, Bavaria, during the year 1843.

Wurtzburg, Bavaria, during the years 1781 to 1785 inclusive; also during a period of five years, whose date is not preserved.

(Nos. 311 to 340.)

Austrian Empire.

Observed at the following places, viz. :-

Adelsberg, Illyria, during the years 1850 and 1851.

Althofen, Hungary, during the years 1850 and 1851.

Botzen, Tyrol, during the year 1851.

Brunn, Moravia, during the years 1848 to 1851 inclusive.

Buda, Hungary, during the years 1782 to 1785, and by Meyer, 1842 to 1844, both inclusive.

Czaslau, Bohemia, during the year 1848.

Debreczin, Hungary, during the years 1854 to 1858 inclusive.

Deutschbrod, Bohemia, during the years 1848, 1849 and 1850.

Funfkirchen, Hungary, during the years 1819 to 1832 inclusive.

Graetz, Styria, during the years 1837 to 1845 inclusive.

Hermannstadt, Transylvania, during the year 1851.

Hohenpeissenberg, 1 Bavaria, during the years 1846 to 1850 inclusive

Ittendorf, Bavaria, from December, 1854, to November, 1857, inclusive.

Klagenfurth, Illyria, during the years 1848 to 1851 inclusive, and ten months of 1855.

Kremsmunster, Austria, during the years 1802 to 1851, and 1855 to 1857 both inclusive.

Lemberg, Galicia, during the years 1854 to 1858 inclusive.

Obir, Illyria, during the years 1866 to 1868 inclusive.

Olmutz, Moravia, during the year 1850, except October and November.

Ofen. (See Buda.)

Pilsen, Bohemia, during an aggregate period of 29 months in the years 1848, 1849 and 1850.

Sagritz, Austria, from June, 1848, to December, 1850, inclusive

St. Paul, Illyria, during an aggregate period of 18 months in the years 1848 and 1850.

St. Peter, Austria, from May, 1850, to December, 1851, inclusive.

Salzburg, during the years 1847 to 1852 inclusive.

San Lorenzo, Illyria, during the year 1851.

Selau, Bohemia, during the years 1848 and 1849.

Stanislau, Galicia, during the year 1851.

Steubenbach, Bohemia, from December, 1848, to December, 1850, inclusive.

Trieste, Illyria, during the years 1841 to 1850 inclusive.

Vienna, Austria, from January, 1798, to November, 1851, and from December, 1854, to May, 1856, both inclusive.

Wartburg, Hungary, during the years 1823 to 1827.

Winterberg, Bohemia, from April, 1848, to December, 1850, inclusive.

(Nos. 351 to 367.) Russi

Russia and Sea of Azof.

Observed at the following places, viz.:-

Astrachan, during the years 1824 to 1834, 1837, 1838, 1845 to 1850, all inclusive; 1853 and 1857, and also, in the Addendum to this zone, the Port of Astrachan, for the years 1845 to 1866 inclusive.

Azof (Sea of), in the months of April, May and June; date not preserved.

Charkov, by Prof. Lapschin, at the University of Charkov, during the years 1844 to 1848 inclusive; also by Mr. Morosow, during the years 1851, '52, '54, '59, '62, '63, '64, '66 and '67.

Dniestrovski Tzaregradsky Znak, during the years 1865 and 1866, by Glazoff.

Ekaterinoslav, during the years 1833 to 1842 inclusive.

Gouriev, by Chevalier Kahnikoff, from October, 1828, to April, 1829, inclusive.

Kertsch, during a period of two years; date not preserved.

Kischinev, by Denjink, from June, 1844, to June, 1854.

Orlov, by Dersken, during the years 1842 to 1854 inclusive.

Lougan, the years 1838 to 1850 incl., 1853 and 1857. Computations for the first series by Spasske.

Nijne Tchirsk, from December, 1852, to November, 1853, inclusive, and 1857.

Nikolaief, during the years 1827 to 1835 inclusive; also observed in 1865 and 1866.

Odessa, from March, 1820, to February, 1825, inclusive, and during the years 1829 and 1830.

Otchakof, during the years 1865 and 1866, by Zasabine.

Poltava, during the years 1824 to 1831, and 1836 to 1848, both inclusive, and 1857.

Taganrog, by Mann, during the years 1817 to 1832 inclusive.

Observed at Dniestrovski, Odessa and Otchakof, using only one-fifth of the numbers for Odessa (No. 353), in order to give them their proper weight.
 Seasons for the years 1855 and 1866 only.
 Allowing for calms for the entire period in the same proportion as in the years 1850 and 1857.
 Computed from the resultants for the estatons.

(Nos. 358 to 362.)

Resultants combined, giving weight in proportion to the number of years.

² Computed from the resultants for the seasons.

 3 This result for 19 years, combined with that of Mr. Kahnikoff for the years 1837 and 1838, viz., N. 45° E. .164, gives as the annual resultant for 21 years N. 81° 57′ E. .16.

(Nos. 367(a, b, c).)

Kirghiz Steppes.

Baron Humboldt, in his work on Central Asia, speaking of the observations of M. Platon de Tchihatcheff, in the region northeasterly from the Caspian Sea-lat. 46° to 51°, and long. 52° to 56°—says that from December 1st, 1839, till April 1st, 1840, a period of 121 days, the wind blew for more than 79 days, generally from E.N.E. and N.E., sometimes from the east.1

Chevalier Kahnikoff in a private letter gives a description of the winds of this region, of which the following is a translation :-

"Having compiled the journals of travels in the Kirghiz Steppes, between the Caspian Sea, Aral Lake, and the Mouhogjars Mountains, from 1826 to 1841 inclusive, I find the resultant direction of the winds over this region to be S. 89° 12′ W., and its ratio .307.2

"At the east of the Mouhogjars Mountains (i. e. east of 75° from Ferros), N.E. winds predominate, a fact that appears not only from direct observations, but also from the instinct of animals that burrow, very common in this part of the Steppe, which always open their holes towards the southwest, so that the prevailing N.E. wind may not fill them with sand. This direction is the prevailing one as far as the meridian and latitude of Bokhara, as I have shown by my observations in that city, published in Humboldt's Asie Centrale."4

¹ No. 367(a). ² No. 367(b). ³ Longitude 56° 53' E. from Greenwich. Mount Gruk, the highest peak of these mountains, is in about latitude 48° 40' and longitude 58° 50'. 4 No. 367(c).

(Nos. 368 to 375(a).) Central and Eastern Asia.

Observed at the following places, viz.:-

Aniva Bay, in District of Sachalin, Siberia, from October, 1853, to May, 1854, inclusive, by Lieutenant Radanowskij.

Fort Aralskoe (or Raimsk), Turkestan, from December, 1850, to November, 1853, inclusive.

Fort No. 1, Turkestan, during the years 1865 and 1866, by Proscouranoff, also 1857.

Fort Ouralsk, Turkestan, during the years 1865 and 1866, by Witkewitch.

Fort Perowski, Turkestan, during the year 1857.

Urga, Mongolia, by Dr. H. Frietsche, during the year 1870 and ten months of 1871; also by Jsodbojef, during the years 1870, 1871, in Addendum at the end of this Zone, where the force is given on a scale from 1 to 10.

ZONE No. 10.

Latitude 40° to 45° North.

The data for the study of the winds of this zone consist of observations made at over a thousand permanent stations on land, for an aggregate period of over 4414 years; on the Atlantic and Pacific Oceans for over 24 years, and some reported to the British Board of Trade from the Black Sea. The distribution is as follows:—

Where observed.	No. of Stations.	Aggregate length of time.
Pacific Ocean, America west of the Mississippi River, America east of the Mississippi River, Atlantic Ocean, Europe, Black Sea, Asia,	161 795 50	$\begin{array}{c} 3319 \; \mathrm{days} = 9 \; \mathrm{years} \; 1 \; \mathrm{month.} \\ 553 \; \mathrm{years,} \; \mathrm{besides} \; \mathrm{general} \; \mathrm{observations} \; \mathrm{by} \; \mathrm{Nicollet.} \\ \mathrm{over} \; 3491 \; \mathrm{years.} \\ 5467 \; \mathrm{days} = \mathrm{nearly} \; 15 \; \mathrm{years} \\ \mathrm{over} \; 343\frac{1}{2} \; \mathrm{years.} \\ \mathrm{?} \\ \mathrm{about} \; 26 \; \mathrm{years.} \end{array}$

(Nos. 1 to 10.) Pacific Ocean, east of longitude 180°.

Computed from observations for an aggregate period of 1670 days, collected and classified, from the logs of numerous sailing vessels, at the United States Naval Observatory, under the direction of Captain M. F. Maury, Superintendent.

33 January, 1875.

(Nos. 11 to 21.) California, north of latitude 40°.

Observed at the following places, viz. :-

Camp Bidwell, by Post Surgeons, from September, 1866, to December, 1869, inclusive.

Camp Gaston, by Post Surgeons, for an aggregate period of $7\frac{1}{2}$ years, in the years 1860 to 1869 inclusive.

Crescent City, by Robert B. Randall, from July, 1859, to January, 1860, inclusive.

Fort Crook, by Post Surgeons, for an aggregate period of $8\frac{1}{3}$ years, in the years 1860 to 1869 inclusive.

Fort Humboldt, by Post Surgeons, for an aggregate period of 11 years, in the years 1854 to 1866 inclusive.

inclusive. For Jones, by Post Surgeons, for an aggregate period of $4\frac{1}{2}$ years, in the years 1853 to 1858 inclusive.

Fort Lincoln, by Post Surgeons, for an aggregate period of 32 months, in the years 1866 to 1869 inclusive.

Fort Reading, by Post Surgeons, for an aggregate period of 40 months, in the years 1852 to 1856 inclusive.

Fort Ter-waw, by Post Surgeons, for an aggregate period of 18 months, in the years 1860 and 1861.

Meadow Valley, by J. H. Whitlock, C. A. Canfield and M. D. Smith, for an aggregate period of 17 months, in the years 1860 and 1861.

(Nos. 73 to 77.) Minnesota, south of latitude 45°.

Observed at the following places, viz.:-

Afton, by Dr. B. F. Babcock, for an aggregate period of 34 months, in the years 1865, 1866, 1867 and 1869.

Bowles Creek, by Andrew Stouffer, during the month of December, 1865.

Chatfield, by T. F. Thickstun, for an aggregate period of 13 months, in the years 1860 and 1861. Danville, by Thomas A. Kellett, during five months of the year 1868.

Fort Ridgely, by post surgeons, for an aggregate period of nearly 13 years, in the years 1853 to 1867 inclusive.

Fort Snelling, by post surgeons, for an aggregate period of over $37\frac{1}{2}$ years, in the years 1822, 1824 to 1858, and 1867 to 1869, both inclusive.

(Nos. 73 to 77.)

Minnesota.—Continued.

Hastings, by T. F. Thickstun, from June, 1861, to May, 1862, inclusive.

Mankato, by William Kilgore, during the month of August, 1864.

Minneapolis, by William Cheney, for an aggregate period of over five years, from November, 1864. to December, 1869, inclusive.

New Ulm, by Charles Roos, from February, 1864, to December, 1869, inclusive.

Pajutazee, by Rev. S. R. Riggs, for an aggregate period of 24 months, in the years 1860, 1861 and 1862.

Red Wing, by Rev. Jabez Brooks, during the months of November and December, 1855, and April, 1856; and by A. M. Stephens, during the first eight months of the year 1867.

Rochester, by Alfred Milmine, during the first three months of the year 1869.

St. Paul, by Rev. A. B. Patterson, for an aggregate period of nearly 7 vears, in the years 1861 to 1869 inclusive; and by J. M. Heimstreet, from October, 1866, to January, 1867, inclusive.

Sibley, by C. W. and C. E. Woodward, for an aggregate period of over 51 years, in the years 1865 to 1869 inclusive.

Source of the Des Moines, by Nicollet.

Travers des Sioux, by Rev. R. Hopkins, during the months of March and April, 1851.

Wabashaw, by Spenser L. Hillier, during the month of December, 1857.

Northern Iowa.

Observed at the following places, viz .:-

Algona, by F. McCoy and Miss Elizabeth McCoy, for an aggregate period of $3\frac{3}{4}$ years, in the years 1861 to 1865 inclusive; and by James H. Warren, from April, 1867, to December, 1869, inclusive; also by Philip Dorweiler, at a point ten miles southwest of Algona, for an aggregate period of over three years, in the years 1866 to 1869 inclusive.

Ames, by J. M. Cotton, during the month of September, 1869.

Bangor, by Isaac M. Gidley, for an aggregate period of 8 months in the years 1861 and 1863.

Boonsboro, by E. Babcock, for an aggregate period of 21 months, in the years 1867, 1868 and 1869.

Border Plains, by G. C. and W. K. Goss, for an aggregate period of $2\frac{1}{2}$ years, in the years 1856, 1857 and 1858.

Dakota, by William O. Atkinson, from October, 1867, to March, 1868, inclusive.

Fort Dodge, by post surgeons, for an aggregate period of 22 months in the years 1851, 1852 and 1853; and by C. N. Jorgenson, from March, 1867, to March, 1869, inclusive.

Iowa Falls, by Nathan Townsend, from November, 1863, to December, 1869, inclusive, except the month of February, 1868.

Marble Rock, by H. Wadey, for an aggregate period of 28 months in the years 1867, 1868 and 1869.

Mineral Ridge, by J. T. Sullivan, during the last seven months of the year 1869.

Osage, by Rev. Alva Bush, from April, 1866, to February, 1867.

3 Computed from the resultants for the seasons.

(Nos. 81 to 83.) Southern Iowa, and Missouri north of latitude 40°.

Observed at the following places, viz .:-

Athens, Missouri, by John T. Caldwell, for an aggregate period of 29 months, in the years 1863 to 1866 inclusive.

Bethany, Missouri, by D. J. Heaston, during the months of January, February, May and June, in the year 1860.

Canton, Missouri, by George P. Ray, for an aggregate period of nearly six years, in the years 1862 to 1868 inclusive; also by J. M. Parker, during the month of April, 1868.

Centreville, Iowa, by Rev. John C. Clyde, at the request of the author, from January to June inclusive, in the year 1870.

Des Moines, Iowa, by Rev. J. A. Nash, for an aggregate period of 20 months, in the years 1865, 1866 and 1867.

Edinburgh, Missouri, by John E. Vertrees, from September, 1866, to January, 1867, inclusive.

Fort Des Moines, Iowa, by post surgeons, for an aggregate period of 26 months, in the years 1843 to 1846 inclusive.

Kirksville, Missouri, by Robert Byers, for an aggregate period of 22 months, in the years 1860, 1861 and 1862.

Lancaster, Missouri, by John M. Wethersford, from June to November inclusive, in the year 1859.

Luray, Missouri, by B. P. Hannan, from June to October inclusive, in the year 1859.

Newton, Iowa, by A. Failor, during the last five months of the year 1869.

Pella, Iowa, by E. H. A. Scheeper, for an aggregate period of 21 months in the years 1854, 1855 and 1856.

Trenton, Missouri, by Thomas J. Conkling, during the month of August, 1859.

(Nos. 92 and 93.)

Southwestern Wisconsin.

Observed at the following places, viz.:-

Baraboo, by M. C. Waite, for an aggregate period of 53 years, in the years 1852 and 1864 to 1869 inclusive.

Bloomfield, see Geneva.

Geneva, by Wm. H. Whitney, for an aggregate period of 67 months, in the years 1863 to 1869 incl. Kilbourn City, by James H. Bell, for an aggregate period of 14 months in the years 1861 and 1862. New Lisbon, by John L. Dunegan, for an aggregate period of 28 months, in the years 1867, 1868, and 1869.

Prairie du Chien, by United States Army surgeons, at Fort Crawford, for an aggregate period of 162 years, in the years 1822, 1824, and 1831 to 1845 inclusive.

Platteville, by Dr. J. L. Pickard and A. K. Johnson, for an aggregate period of nearly six years in the years 1854 to 1859 inclusive.

1 Including Platteville in Southwestern Wisconsin. 2 From this table we obtain the following summary of results: Spring. Summer. Autumn. Winter. The year.																		
								-	,	-				-		-		-

	Spring.	Summer.	Autumn.	Winter.	The year,
Average velocity of all winds in miles per hour Velocity in mean direction, on the supposition that the winds	7.30	4.55	6.49	6.25	6.15
from every point of the compass move with the foregoing average velocity. True velocity in mean direction, giving to the winds from the several points of the compass each their own average velocity,	.58	.80	1.45	1.86	1.09
as shown in the table above	.67 +.09	.96 +.16	1.51 +.06	1.73 —.13	1.10 +.01

³ Computed from the resultants for the seasons.

From the dates given above it will be seen that we have only three-quarters as many observations in the first half of the year as in the last half; and so to equalize their influence on the general result for the year, the former have, in this table, been multiplied by 4, and the latter by 3. The direction of the resultant for the year is $S.~89^{\circ}$ 0' W., and its ratio to the sum of the winds .25.

¹ Capt. A. D. Perkins and G. W. Bowlsby.

127. Western Reserve College, Hudson.

Prof. Elias Loomis, who made these observations with great minuteness in regard to the direction of the wind, resolved them in the direction of the cardinal points, as given in the table below. For the surface winds, both the number of observations and the estimated force were taken into account; for the motion of the clouds, the former only.

If we combine the observations of the motion of the clouds at 9 o'clock A. M. with those at 3 o'clock P. M., the direction of the resultant becomes S. 88° 37′ W., and the observations by the vane show about the same result, if we take into account only their number. But if we assume that the figures by which the force is indicated in the register are proportional to the velocity of the wind, and make an allowance accordingly, the direction becomes N. 85° 17′ W. The average force of each of the several winds, deduced from observations made during the year 1841 and parts of 1838 and 1840, and expressed in terms of the force numbers used in the registers, was as follows:—

made during the year 1841 and parts of 1838 and 1840, and expressed in terms of the force numbers used in the registers, was as follows:—

North 2.12, N. by E. 2.39, N.N.E. 2.20, N.E. by N. 2.09, N.E. 2.23, N.E. by E. 2.00, E.N.E. 1.80, E. by N. 1.79; East 2.00, E. by S. 2.16, E.S.E. 1.71, S.E. by E. 1.86, S.E. 1.67, S.E. by S. 1.37, S.S.E. 1.59, S. by E. 1.78; South 1.85, S. by W. 1.77, S.S.W. 1.79, S.W. by S. 1.68, S.W. 2.03, S.W. by W. 1.98, W.S.W. 2.20, W. by S. 2.41; West 2.46, W. by N. 2.83, W.N.W. 2.90, N.W. by W. 2.87, N.W. 2.84, N.W. by N. 2.43, N.N.W. 2.52, N. by W. 2.30.

¹ The numbers in this column express the ratio that the resultants bear to the sum of the winds, after being resolved in the direction of the cardinal points, and are somewhat less than if they had been computed from the original observations.

¹ Prof. C. Dewey appends the following note to the observations at this place: "The country around this station is a rolling level, with no local obstructions which might influence the direction of the winds. Lake Outario is five miles to the north, and there are slight hills to the south which have no influence upon the winds. The surface winds are observed to differ from the upper currents. From 1836 till about 1844 the indications of the wind vane were recorded, but subsequently the direction as shown by clouds. This difference has been ascribed to the fact that the waters of Lake Ontario acquire and retain till late the summer's heat, and thus give a tendency of the surface current of air towards them."

1 From this table we obtain the following summary of results:-

	Spring.	Summer.	Autumn.;	Winter.	The year.
Average velocity of all winds in miles per hour	6.39	6.04	5.95	6.72	6.27
Velocity in mean direction, on the supposition that the winds from every point of the compass move with the foregoing average velocity	1.84	2.61	2.07	1.75	2.06
True velocity in mean direction, giving to the winds from the several points of the compass each their own average velocity,			1		
as shown in the table above	2.08	3,00	2.62	2.39	2.50
Excess of the latter over the former	+.24	+.39	+.55	+.64	+.44

² Computed from the resultants for the seasons.

² From this table we obtain the following summary of results:—

	Spring.	Summer.	Autumn.	Winter.	The year.
Average velocity of all winds in miles per hour Velocity in mean direction, on the supposition that the winds	8.39	5.69	6.70	8.60	7.34
from every point of the compass move with the foregoing average velocity True velocity in mean direction, giving to the winds from the	1.75	1.38	1.72	3.09	1.72
several points of the compass each their own average velocity, as shown in the table above	2.29	1.03	1.67	3.26	1.78
Excess of the latter over the former	+.54	35	05	+.17	+.06

³ Computed from the resultants for the seasons.

1 From this table we obtain the following summary of results:-

	Spring.	Summer.	Autumn.	Winter.	The year.
Average velocity of all winds in miles per hour	6.43	3.99	4.59	6.18	5.30
Velocity in mean direction on the supposition that the winds from every point of the compass move with the foregoing average velocity. True velocity in mean direction, giving to the winds from the	1.86	1.02	1.71	2.91	1.77
several points of the compass each their own average velocity, as shown in the table above	2.21 +.35	1.10 +.08	1.73 +.02	3.24 +.33	1.91 +.14

Computed from the resultants for the seasons.
 Computed from observations recorded from 16 points.

Observed at Salamanca, Valladolid, Villaviciosa, Madrid and Soria.
 Observed at Saragossa, Huesca, Balaguer and Barcelona.
 Computed from the resultants for the seasons.

(Nos. 355 to 368.)

Southern France.

Observed at the following places, viz .: -

Bagneres de Bigorre, by F. W. Lyte, during the year 1864.

Bordeaux, 1837 to 1846, and by Abrai, during the years 1847 to 1851, and 1853 to 1856, all inclusive.

Eaux Bonnes, by Dr. B. Schnepp, from June to September inclusive, 1864.

Marseilles, during the years 1823 to 1840 inclusive, and by B. Valz, during 1847, 1848, and from 1850 to 1860 inclusive.

Montpelier, during a period of probably 37 years; date not preserved.

Orange, by Gasparin, during the years 1848, 1849 and fourteen earlier years whose date is not preserved.

Pau, by E. Oliphant, for an aggregate period of 12 months in the years 1866, 1867 and 1868.

Rodez, by Blondeau, from October, 1845, to September, 1847, and during the years 1848 to 1852, both inclusive.

St. Hyppolyte de Caton, by C. d'Hombres, during the years 1837 to 1853 inclusive.

Toulouse, by Marconelle, during the years 1747 to 1756 inclusive, and by Petit, during the years 1839 to 1847, 1849, 1850, 1851, 1853, 1855 to 1857, and 1859 to 1862, all inclusive.

Computed from the resultants for the seasons.

(Nos. 369 to 381.) Italy, Dalmatia, Turkey and the Black Sea.

Observed at the following places, viz .:-

Black Sea. Neither date nor length of time ascertained.

Bologna, Italy, during the years 1784 and 1814 to 1858 inclusive.

Constantinople, Turkey, by Rev. H. G. O. Dwight, for the author, from November 21st, 1839, to July 13th, 1841.

Genoa, Italy, during the month of March, 1843.

Mentone, Italy, by D. A. Freeman, for 15 months, in the years 1864, 1865 and 1866.

Naples, Italy, during the years 1833 to 1860 inclusive.

Nice, Italy, by M. Teysseire, during March and July to December inclusive, in the year 1864.

Parma, Italy, during 43 months in the years 1841, 1855, 1856 and 1857.

Ragusa, Dalmatia, during the year 1851.

Rome, Italy, during the years 1783 to 1785, and 1850 to 1860, both inclusive.

St. Zeno, Italy, during the year 1781.

¹ The following remarks by Mr. Dwight accompanied these observations:—
"In regard to my record of the winds, I must say that if I had been situated where I had a high vane to guide me, the table would probably have shown some slight veerings to the east or west, which do not now appear. There is, however, no doubt of the fact that the wind here, as a general thing, blows either from the northeast or southwest. A wind from either of the four cardinal points never continues long in Constantinople. During the fifteen or sixteen years that I have been here, I have noticed that our prevailing wind in summer is northeast. Indeed, from July to October it is so constantly and regularly from that quarter as to be almost a monsoon; and during that period the nights are very apt to be calm. The wind begins to blow gently soon after sourise, and it increases until, say two o'clock, when it not unfrequently blows very strong, and then gradually dies away, and soon after sunset it becomes calm again. During the prevalence of this wind in summer, the atmosphere is usually clear, or, at least, there are only flying clouds, without rain; but in winter the north wind always brings clouds and rain. When the south wind blows in summer, it is usually a mere land breeze, and I have often myself observed, in gassing up the Bosphorus on a summer's day, when the wind is southwest at the entrance of the Bosphorus, into the Sea of Marmora, it is northeast at the northern end of the same strait, i. e. as it issues from the Black Sea. I have known it to blow all day thus in opposite directions, the two winds meeting at the middle of the strait, where it was perfectly calm.

"One fact you will probably notice from my table, and that is, that there is far more southerly wind in winter than in summer. And this leads me to say a word in reference to your question, whether I know of any local cause, besides the direction of the straits, that would affect the wind? About seventy or eighty miles south of us is the high range of Mount Olympus (not Thessalian, but Bythnian), whose summit is at least eight thousand feet above the sea level, and, of course, in winter it is covered with an immense mass of snow. This has been supposed to be the chief cause of our having so much southerly wind in winter. I do not give this as my opinion, however, but I simply state the fact of such a mountain being in such a relative position to the capital, and also an as my opinion, nowever, but I simply state the lact of such a mountain being in such a relative position to the capital, and also an inference that has been drawn from that fact. I have always noticed that our coldest weather in winter comes when the southerly wind first begins to blow, which I account for on the supposition that such a wind brings first over us the frozen atmosphere of Olympus, and other high ranges of mountains in the interior. But if the wind continues two or three days (and it sometimes does two or three weeks uninterruptedly in winter), it is sure to bring mild and almost summer weather. The barometer here invariably sinks with a southerly wind, and the rain-point is much higher with a northerly than with a southerly wind. I have sometimes noticed an alarming fall in the barometer, but I soon learned not to anticipate any nuusual storm from that, if the wind was just coming from the south or southwest. Our heaviest blows and our most copious rains ordinarily come just as the wind is changing from a southerly to a northerly direction.

"As you are interesting yourself in the study of the winds, I will just mention one more fact, though an isolated one. (I wish I had more of them.) Three years ago I was in Smyrna, in the antumn, when we had one of the most dreadful gales I have experienced on these shores. It came in the night, and blew for four or five hours, I think, with the greatest violence, so that much damage was done to the shipping. I took particular notice of the wind, and found that the same gale had been felt, if possible, still more severely in Constantinople, though somewhat later, i.e. two or three hours perhaps; and an observant sea captain of my acquaintance, who happened to be off this port at the time, informed me that the wind here was from the southwest, i.e. directly opposite that of Smyrna. I must say, however, that as I took no note of it at the time, I am not positively certain it was later at As you are interesting yourself in the study of the winds, I will just mention one more fact, though an isolated one. Constantinople. It may have been so much earlier instead of later, though my strong impression is that my first statement is correct. The main point, however, to which my mind was directed, was the fact that in the same gale the wind blew from opposite quarters at Smyrna and at Constantinople. The distance between the two cities, by sea, is estimated at about 350 miles, though by

an air line it must be considerably less.

(Nos. 382 to 396(a).) Southeastern Russia, Asia Minor and Trans-Caucasia.

Observed at the following places, viz::-

Alagyr, Russia, during the months of October and November, 1853.

Alexandropol, Trans-Caucasia, during the years 1853, 1858 to 1865 inclusive, and the summer and autumn of 1852.

Alexandrovskaya, Stanitza, Russia, by Dr. Land, during the years 1848, 1849 and 1850.

Bakou, Trans-Caucasia, during the years 1852, 1853, 1865, 1866, 1870, 1871; the two latter years by Morganoff and Martschenko.

Derbend, Russia, during the years 1852, 1853.

Grosnoe, Russia, during the years 1870, 1871, by Toptschewski and Klossowski.

Gudaur, Trans-Caucasia, by Federof, three years, 1870 to 1872.

Koutais, Trans-Caucasia, from January, 1852, to August, 1853, inclusive.

Poti, Trans-Caucasia, during the years 1870, 1871, by Lupanoff.

Redut-Kaleh, Trans-Caucasia, from December, 1852, to November, 1853, inclusive.

Sevastopol, Russia, during the years 1865 and 1866, by Seredovitch.

Simferopol, Russia, by Milhausen, during a period of 29 years, 1822 to 1853 inclusive.

Stanitza. See Alexandrovskaya.

Stavropol, from December, 1864, to November, 1866, inclusive.

Tiflis, Trans-Caucasia, at the Observatory, hourly, from June, 1844, to May, 1847, December, 1849, to November, 1851, December, 1852, to November, 1853, and December, 1856, to November, 1857, all inclusive.

Trebizond, Asia Minor, during the year 1836.

Władikawkas, Russia, during the year 1872.

Note.—By "Russia" in the heading of this chapter is intended Russia in Europe, north of the Caucasian chain; and by Trans-Caucasia, the Russian provinces south of the Caucasian chain.

1 Rev. N. Benjamin, in a letter to the author, makes the following remarks in regard to the winds at this

"Rev. N. Benjamin, in a letter to the author, makes the following remarks in regard to the winds at this place, having resided there for some years:—
"The prevailing winds at Trebizond are northwest winds and easterly winds. The sirocco also sometimes prevails. Rain storms, which are very frequent, are almost invariably with a wind blowing from the northwest. The clear and pleasant weather was almost as uniformly with an easterly wind, and I also quite generally observed that the barometer was lower with an east wind when quite clear, than with a northwest, or a northwind accompanied by an obscure sky, and even with rain. So that we had often the extraordinary phenomenon of the barometer rising as the storm was coming on, and standing very high during a protracted rain, and sink-

ing on the return of clear weather.

"I have not been able to form any satisfactory conclusions in regard to the local causes which affect the direction of the winds at Trebizond, and can only say that the whole country in the rear of that place is mountainous to an unusual degree."

² M. Khanikoff, in a letter to the author, gives the following directions of the resultants for the different seasons of 1852 and 1853, and for the entire years, viz.:—

			1852.	1853.
Spring .			S. 42° 25′ W.	S. 3° 22′ W.
Summer .			S. 88 49 W.	S. 72 53 W.
Autumn .			S. 29 28 E.	S. 53 57 E.
Winter .			N. 89 4 E.	S. 58 22 E.
The year			S. 17 29 E.	S. 19 49 E.

³ Chevalier Khanikoff makes the directions of the resultants for the year 1852 as follows, viz.: Spring, N. 78° 38′ W.; Summer, S. 89° 14′ W.; Autumn, N. 40° 2′ E.; Winter, N. 61° 46′ E.; The year, N. 2° 22′ E.

¹ Months for the last 8 years only. Chevalier Kahnikoff makes the directions of the resultants for the year 1852 as follows, viz.: Spring, N. 6° 25′ E.; Summer, N. 1° 45′ E.; Autumn, N. 52° 57′ W.; Winter, N. 10° 55′ W.; The year, N. 8° 16′ W.
² Resultants at Nos. 388 to 392 inclusive, combined by plotting.
³ Chevalier Kahnikoff makes the direction of the resultants for the year 1852 as follows: Spring, S. 31° 49′W.; Summer, N. 79° 34′ W.; Autumn, S. 54° 22′ W.; Winter, S. 57° 22′ W.; The year, S. 71° 10′ W. He does not give the relative prevalence, so that we cannot combine his results with those above for 1853.
⁴ Chevalier Kahnikoff makes the direction of the resultants for the year 1852 as follows: Spring, N. 51° 5′ W.; Summer, N. 5° 16′ E.; Autumn, N. 24° 17′ E.; Winter, N. 76° 22′ W.; The year, N. 20° 14′ W. He does not give the relative prevalence, so that we cannot combine his results with those above for 1853.
⁵ Computed from the resultants for the seasons.

(Nos. 397 to 402.)

Central and Eastern Asia.

Observed at the following places, viz.:-

Foordan, Mantchooria, by Dr. H. Fritsche, from July, 1870, to January, 1871.

Hakodade, Island of Jesso, Japan, during the years 1840, 1841 and 1842; and by officers of the U.S. Naval Expeditions under command of Commodores Perry and Rogers, in the summer of 1853 and 1856.

Krasnovodsk, from December, 1869, to August, 1870, and from December, 1870, to February, 1871, both inclusive, by Denissof and Pavlof-Sylvansky.

New Chwang, Mantchooria, from November, 1861, to November, 1862.

Novo Petrowsk, Eastern shore of the Caspian, during the years 1849 to 1856 inclusive.

Olga Bay, Province of Eastern Siberia, by Dr. Wulfius, 5 months, December, 1858, to April, 1859.

Possiet Bay, Province of Eastern Siberia, by Tscherkasskij, 2 years, 1860-61.

Taschkent, Central Asia, one year, 1868. Observed from 6 o'clock A. M. to 10 o'clock P. M. every two hours, with omissions. Observer's name unknown. Also, by Michelson, three times a day, in 1871, for January and February, and from June to December inclusive.

¹ The following is an extract from a letter from Dr. Frietsche to Dr. W. A. P. Martin, of Pekin:—
"I remained more than six months at a small place half way between the lake Hanka and Vladivostok, near the ruins of the town marked on the Mantchoo maps under the name of Foordan. The village lies in the broad valley of the river Sooi-fun, a low range of hills separating it from the lake Hanka; on the sonth it is also protected by a wooded range of hills, across which the river Sooi-fun runs through a narrow pass. I arrived at Foordan on the 10-22 July, 1870. In this season the S. E. winds reign in the country, and they bring with them rain clouds. Rain was frequent in the Sooi-fun valley, but was not accompanied by thick fogs, as it is in the country near the sea. The wind was not so strong as on the sea-shore, or on Lake Hanka, which is not protected by hills from the S. E. The rainy season continued, with some changes, up to the end of autumn; but in October, and up to the middle of November, the weather was generally fine, warm and mild; although there was a slight fall of snow sometimes. In December N. W. winds began to blow, bringing severe cold with them—the temperature was as low as —30° Re. Still in the Foordan region the winter winds were not so continuous as in the Valdivostok and Hanka. The next year the southerly winds began early in April, but they were also intermixed with northerly winds."

Addendum to Zone No. 10.

Sevastopol, observed by Admiral Arkass, from 1840 to 1851, twelve years. Nikita, south coast of Crimea, in 1830, 1855 and 1858-65, ten years, old style. Karabagh, south coast of Crimea, from July, 1866, to September, 1867. Grimea.

ZONE No. 11.

Latitude 35° to 40° North.

The data for the study of the winds of this zone consist of observations made at over 444 stations on land, for an aggregate period of over 1941 years; and on the Atlantic and Pacific Oceans for over 39 years. The distribution is as follows:—

Where observed,	No. of Stations.	Aggregate length of time.
Pacific Ocean,		7084 days = 19 years 3 months.
United States west of the Mississippi,	165	over 561 years 6 months.
United States east of the Mississippi,	222	1215 years 6 months.
Atlantic Ocean,		over 20 years.
Azore Islands,	7	23 years 6 months.
Portugal and Spain,	15	48 years, also other observations not regu-
Greece and Islands of the Mediterranean,	4	over 13 years 6 months. [larly recorded.
Northern Africa,	7	46 years.
Asia,	24	over 34 years 4 months.

(Nos. 1 to 9.) Pacific Ocean, east of longitude 180°.

Computed from observations for an aggregate period of ten years, collected and classified from the logs of numerous sailing vessels, at the United States Naval Observatory, under the direction of Capt. M. F. Maury, Superintendent.

(Nos 38 to 50.)

New Mexico, north of latitude 35°.

Observed at the following military posts, by officers connected therewith, viz. :-

Place of observation.	Aggregate length of time.	Date.					
Abiquiu,	yrs mos.	July, August and September, 1851.					
Albuquerque,	13 7	1849 to 1861 and 1863 to 1867, both inclusive.					
Camp Cimarron,	1 0	1868 and 1869.					
Camp Plummer,	1 10	1867, 1868 and 1869.					
Cantonment Burgwin,	5 2	1854 to 1860 inclusive.					
Ceboletta,	2 1 3 1	1849, 1850 and 1851.					
Fort Bascom,	3 1	1864, 1865, 1866 and 1869,					
Fort Fauntleroy,	0 11	1860 and 1861.					
Fort Lowell,	0 9	1868 and 1869.					
Fort Union,	16 7	1851 to 1869 inclusive.					
Fort Wingate,	6 4	1863 to 1869 inclusive.					
Laguna,	0 2	1852.					
Las Vegas,	1 7	1850 and 1851.					
Rayado,	0 2	1851.					
Santa Fé (Fort Marcy),	14 8	1849 to 1867 inclusive.					
Taos,	0 2	May and June, 1850.					

(Nos. 38 to 43.)

New Mexico .- Continued.

Observed at Ceboletta, Laguna and Forts Fauntleroy and Wingate.
 Abiquiu, Camp Plummer, Cantonment Burgwin, Fort Lo ell and Taos; upper and lower currents combined.
 Computed from the resultants for the seasons.

2 Rev. N. O. Preston, H. L. Denison, Agricultural College, B. F. Mudge and others.
3 Beside the regular observations reported from this post to the Surgeon-General, and which are embodied in this table, another series, differing somewhat, appears to have been taken during many months of the years 1860 and 1862 to 1866 inclusive, and reported to the Smithsonian Institution. Both the series are embraced in the table for Eastern Central Kansas. The surface winds and the motion of the clouds are combined in the table.

Observed at Burlingame, Council Grove, Fort Riley, Junction City and Manhattan.
 Computed from the resultants for the seasons.

(Nos. 70 to 73.)

² From this table we obtain the following summary of results:—

	Obtang.	Summer.	Autumn,	Winter.	The year.
Average velocity of all winds in miles per hour	11.24	5.72	5.76	4.30	6.75
Velocity in mean direction, on the supposition that the winds from every point of the compass move with the foregoing average velocity. True velocity in mean direction, giving to the winds from the several points of the compass each their own average velocity,	2,22	1.68	.78	.90	.97
as shown in the table above	2.45 +.23	1.59	.92 +.14	1.27 +.37	.61

2 From this table we obtain the following summary of results:-

	Spring.	Summer.	Autumn.	Winter.	The year.
Average velocity of all winds in miles per hour Velocity in mean direction, on the supposition that the winds	6.18	4.75	4.60	7.86	5.85
from every point of the compass move with the foregoing average velocity	1.23	.72	.72	1.80	.82
True velocity in mean direction, giving to the winds from the several points of the compass, each their own average velocity, as shown in the table above	2.00	.56	.65	2.13	1.06
Excess of the latter over the former			07		+.24

³ Computed from the resultants for the seasons.

³ Computed from the resultants for the seasons.

(No. 148.) Delaware, Maryland and Eastern Virginia.

Average result for each month of the year, computed from observations made at 14 different stations, for an aggregate period of $25\frac{1}{3}$ years, previous to the year 1850.

(Nos. 169 to 175b.)

Azores.

Observed hourly from 6 o'clock A. M. till 9 o'clock P. M. (excepting Angra and Delgada), under direction of Consul-General Hunt, on the following islands, viz.:—

Angra, for six years, 1865-70 (three times a day only).

Delgada, for six years, 1865-70 (three times a day only).

Fayal, during the months of June and July, 1840; also at Horta, on this island, by S. W. Dabney, from November, 1862, to October, 1857, inclusive.

Graciosa, during the first twelve days of June, 1840.

St. Mary's, from July 22 to 31, 1840.

St. Michael's, during the months June and July, 1840; also, during the years 1860 to 1869 inclusive.

Terceira, during the same two months.

¹ These latter observations, from 1860 to 1869 inclusive, are quoted by Dr. Buchan, from the Reports of the British Association. The name of the observer is not given.

(Nos. 205 to 208a.) Greece, the Islands of the Mediterranean Sea, and Southern Turkey.

Observed at the following places, viz .:--

Athens, Greece, by Dr. Julius Schmidt, for three years, 1859, 1860 and 1861.

Corfu, Ionian Islands, by D. Mackenzie, during the years 1846 and 1854 to 1859.

Janina, Turkey, by Major R. Stuart, for an aggregate period of 14 months, in the years 1866,

Malta, for an aggregate period of between three and four years, from 1853 to 1859 inclusive.1 Syra, Grecian Archipelago, during eleven days, in the month of December.

Turkey in Asia.

Observed at the following places, viz .:-

Aleppo, Syria, Capt. James Capper, from September, 1747, to September, 1749, inclusive. Cæsarea, Palestine, from Oct. to Feb. of the succeeding year inclusive; date not preserved.

Erzeroom, Armenia, during the year 1836.

Mosul, Mesopotamia, from February, 1854, to December, 1855.

Smyrna, Asia Minor, by Rev. N. Benjamin, from September 5th, 1843, to June 25th, 1844. Tarsus, Asia Minor, from August to November inclusive; date not preserved.

1 The following remarks by Capt. Capper, descriptive of the geographical position of Aleppo, and the local influences by which it is surrounded, accompany these observations.

influences by which it is surrounded, accompany these observations.

"Built on the edge of the great desert, which lies to the E. N. E. and S. E., the sea, with the mountainous country and the Black Sea being to the N. and N. W.; the mountains of Armenia, Mingrelia and Circassia to the N. by E. and N. N. E.; and the deserts of Arabia to the S. E., with the mountainous country on the coast of the Mediterranean Sea to the S. In the cold months the temperature near Aleppowill.be much higher than that of the countries to the N., and consequently the current of cold air will move towards this place from the frozen mountains of Caucasus to restore the equilibrium. In the hot months, on the coutrary, the laud in all the surrounding countries is much hotter than the sea, therefore as the air over the desert to the E. at this season will be much rarefied, the nearest body of cold air will come from the sea to the W. or from the Black Sea to the N. W., to restore the equilibrium; but at other seasons the wind will be more variable, for the temperature of the land and sea being nearly equal, that is, about 56°, the current of air will move different ways in the manner specified in the table."

2 Computed from the resultants for the seasons.

Southern Trans-Caucasia and Northern Persia. (Nos. 215 to 221.)

Observed at the following places, viz. :-

Aralikh, Trans-Caucasia, during the year 1852 and part of 1853.

Astrabad, Persia, during the years 1852 to 1856 inclusive. The observations were made on the island of Ashur-Ade, in the Bay of Astrabad, by officers of the Russian Naval Station.

Lenkoran, Trans-Caucasia, from December, 1851, to November, 1853, inclusive.

Mt. Seir (Ooroomiah), Persia, by Rev. David T. Stoddard, from April, 1852, to March, 1854, inclusive.

Ooroomiah (probably the same as Mt. Seir), Persia, by Rev. Justin Perkins, D.D., for the author, from January 1 to June 18, 1848, and from November, 1849, to November, 1850, inclusive.

Tabreez, Persia, for the author, and through the agency of Rev. Dr. Perkins, who kindly interested himself in the matter, by George A. Stevens, Esq., from September to December inclusive, in the year 1850.

Tehran, Persia, from February to May inclusive, in the year 1850.

¹ These observations were made at the request of the author, through the kind agency of Rev. Dr. Perkins of Coroomiah, and under the direction of William Taylor Thompson, Esq., First Secretary of the British Embassy at Tehran, by Joseph Reed (also connected with the embassy), from February to May inclusive, in the year 1850. Dr. Perkins, in communicating the observations, remarks as follows:—

"Properly to understand these phenomena" (i. e. the winds at Tehran), "it may be well that you have in mind the local situation of Tehran. I will copy a reference to its situation, penned on the spot when I visited it several years ago: 'The local situation of Tehran renders its situation extremely warm, and hemmed in as it is on the north and set he waked mountains, which tower same 5000 or 6000 feet above it in the pear and the wast

on the north and east by naked mountains, which tower some 5000 or 6000 feet above it in the rear, and the vast extent of arid land in the two opposite directions reflecting the heat in summer like a burning desert, the city cannot be otherwise than like a great oven during the warm months of the year, not taking into account at all its relative elevation, which is much less than that of Tabreeze and other cities of Azerbijon.'

"I may add to this notice that the Caspian Sea, lying some seventy or eighty miles north of Tehran, though separated from it by a lofty range of mountains, doubtless affects the character and direction of its winds, and still more probably, the immense salt desert that skirts the plain of Tehran, some fifty miles southeast of

1 Dr. Perkins, in communicating these observations, gives the following description of his plan of observation, and of the local influences to which the winds are subject.

"My residence is on the northeastern declivity of a high mountain. This location may, perhaps, affect the direction of the wind here somewhat, though probably not a great deal. There are, however, some important local causes affecting the winds in this province, which I will here state. About once a month, ordinarily, we have a strong wind, often violent, from the west, which is the simoon or samiel, from the Arabian desert. It usually continues about three days; and though its noxious properties are much neutralized by its passage over a distance of hundreds of miles, and across the high snowy Koordish Mountains, it is still a warm wind offen hely have and with the control of the west of without the control of the west of without the control of the west of without the control of the west of without the control of the west of without the control of the west of without the control of the west of without the control of the west of without the control of the west of without the control of the west of without the west of the w over a distance of hundreds of miles, and across the high snowy Koordish Mountains, it is still a warm wind (often hot) here, and very debilitating to men and animals. And it is often so dy and hot here as to wither and crisp vegetables. . . There is ordinarily, particularly in summer, a morning breeze, lasting two-thirds of the day, from the Lake of Ooroomiah, which is about fifteen miles east of us; and an evening breeze, continuing through the night, from the Koordish Mountains on the west. . . We have also occasionally (once or more in the course of a month), a warm south wind from the hot plains of Mesopotamia, the nearest point of which is about a hundred miles distant; but this wind is distinct from the simoon that comes to us from the Arabian desert. At intervals of a few weeks, and sometimes oftener, we have also a cold invigorating wind from the north, which comes down from the mountains of Ararat.

"The daily lake and mountain breezes continue during the warm part of the year with great regularity, ex-

"The daily lake and mountain breezes continue during the warm part of the year with great regularity, except when interrupted by the simoons, usually once in four, five, or six weeks. Dur there is also much uniformity in the weather, a cloud seldom appearing in the sky."

² Mr. Stoddard, in communicating these observations, adds the following remarks: During this part of the year

"In the summer we have a regular land and sea breeze, the wind coming from the mountains west of us during the night, and from the lake of Ocroomiah, which lies to the east and southeast of us, during the day."

[&]quot;At Tabree2, across the lake, which is about 10 miles distant from us (in a direct line), and hearly east from Ooroomiah, there is daily a strong wind from the Caspian Sea, which is about 150 miles northeast from that city. This wind is very invigorating."

2 For the year 1853 only, Chevalier Kahnikoff makes the directions of the resultants for the year 1852 as

follows :-

Spring. N. 59° 42′ W. N. 58 3 E. Summer. N. 54° 19′ W. S. 0 5 W. Autumn. N. 9°51'E. S. 81 38 W. Winter. N. 46° 59′ W. N. 12 38 W. The year. N. 57° 52′ W. S. 78 4 W. Aralikh, Lenkorán,

(Nos. 222 to 224.)

Central Asia.

Observed, without formal record, at the following places, or in their vicinity, viz.:-

City of Bokhara.

Kara Korum Mountains, Thibet.

Leh, Ladak, Thibet.

Merve, Southern Turkestan.

Shurukhs, Southern Turkestan.

Yarkund, Chinese Turkestan.

Central Asia .- Continued. (Nos. 222 to 224.)

- No. 222. Merve and Shurukhs. Sir Alexander Burns, while travelling between these two places, but nearer to the former, on the 31st of August, speaking of the whirlwinds which are of frequent occurrence in the desert west of the Moorghab river, says: "They appeared to rise from gusts of wind, for the air itself was not disturbed, but by the usual north wind that blows steadily in this desert."
- No. 223. City of Bokhara. Chevalier H. Kahnikoff, who spent some time in this city, in the years 1841 and 1842, remarks as follows, in his work on Bokhara: "The most prevalent winds blow from the north, and more especially from the northeast; they are so constant that during the eight months of my stay at Bokhara, I do not recollect that the wind blew more than ten times from the south." [Quoted by Humboldt, in his Asie Centrale.]
- No. 224. Kara Korum Mountains, Leh and Yarkund. The experience of a native of Ladak, while travelling from Leh to Yarkund, over the Kara Korum Mountains-a journey of 60 days-is narrated by Sir Alexander Burns, who says that leaving Leh late in the month of March, and reaching the mountains in April, he was detained there "a whole week" by the "violence of the north wind and the drifting snow."

(Nos. 225 to 228a.) Northeastern China and Japan.

Observed at the following places, viz. :-

Chefoo, from Nov. 1866, to Feb. 1867, and from March to August, 1869, both inclusive.

Pekin, by the Jesuit missionary, Gachkevitche, during the years 1757 to 1762 inclusive; at the Russian School, during the years 1844 and 1850 to 1855 inclusive; and by the Archimandrite, Drs. Palladius and Fritsch, during the year 1870; and from February, 1871, to January, 1872, inclusive.

Yokohama, by Dr. Gratama, sixteen months, December, 1869, to March, 1871, inclusive. (January, February and March, 30 days each.)

ZONE No. 12.

LATITUDE 30° TO 35° NORTH.

The data for the study of the winds of this zone consist of observations made at over 303 stations on land, for an aggregate period of over 892 years; at sea for over 27 years. The distribution is as follows:—

Where observed.	No. of Stations.	Aggregate length of time.
acific Ocean,		5849 days = 15 years 9 months.
nited States west of the Mississippi,	121	419 years 6 months.
nited States east of the Mississippi,	134	349 years 6 months.
tlantic Ocean,		nearly 11 years 9 months.
lands of the Atlantic,	7	28 years 9 months.
lediterranean Sea and Islands,	1	3 years 6 months.
frica,	14	over 35 years 9 months.
sia,	26	over 55 years 8 months.

(Nos. 1 to 6.) Pacific Ocean, east of longitude 180°.

Computed from observations for an aggregate period of 14 years, collected and classified from the logs of numerous sailing vessels, at the United States Naval Observatory, under the direction of Capt. M. F. Maury, Superintendent.

Observed at Dona Ana and Fort Fillmore.
Computed from the resultants for the seasons.

² Los Pinos and Socorro.

³ Fort Sumner.

(Nos. 44 to 72.)

Texas, north of latitude 30°.

Observed as follows:-

Place of observation.	By whom observed.	leng	regate gth of mc.	Date.
Austin,	J. Van Nostrand & others,	yrs. 22	mos.	1849 to 1851 and 1854 to 1869, both inclusive
Austin Barracks,	Post Surgeon,	2	10	1851, 1852, 1861, 1862, 1866 and 1867.
Bastrop,	J. D. Cunningham,	0	1	1859.
Bonham,	Prof. Solomon Sias,	0	5	1859 and 1860.
Boston,	G. Freese,	1	5	1859, 1860 and 1861.
Bremend,	D + 6	0	9	1869.
Buffalo Springs,	Post Surgeon,	1	4	1867, 1868 and 1869.
Burkeville, Camp Concordia,	Dr. N. P. West, Post Surgeon,	5	5	1856 to 1861 inclusive.
Camp Colorado,	Post Surgeon,	1 3	0 2	1868 and 1869.
Camp Cooper,	Post Surgeon,	1	3	1856 to 1859 inclusive.
Camp Hudson,	Post Surgeon,	1	2	1857 and 1859. 1860 and 1861.
Camp Quitman,	Post Surgeon,	2	4	1858 to 1861 inclusive.
Camp Stockton.	Post Surgeon,	ī	3	1860 and 1861.
Camp Verde,	Post Surgeon,	4	0	1856 and 1860 inclusive.
Chappell Hill.	W. H. Gantt,	o o	7	1866 and 1867.
Concordia,	Post Surgeon,	1	o	1868 and 1869.
Cross Roads,	F. S. Wade,	1	2	1859 and 1860.
Dallas,	John M. Crockett,	0	6	1859.
Fort Belknap,	Post Surgeon,	6	8	1851 to 1859 inclusive.
Fort Bliss,	Post Surgeon,	9	4	1850, 1851, 1854 to 1861 inclusive, 1866, 186
			ì	and 1869.
Fort Chadbourne,	Post Surgeon,	8	4	1852 to 1861 inclusive.
Fort Croghan,	Post Surgeon,	4	3	1849 to 1853 inclusive.
Fort Davis,	Post Surgeon,	7	2	1854 to 1861 inclusive, and 1869.
Fort Gates,	Post Surgeon,	3	3	1849, 1850 and 1851.
Fort Graham,	Post Surgeon,	3	6	1849 to 1853 inclusive.
Fort Lancaster,	Post Surgeon,	4	8	1856 to 1861 inclusive.
Fort McKavett,	Post Surgeon,	G	2 7	1852 to 1859 inclusive.
Fort Martin Scott, Fort Mason,	Post Surgeon, Post Surgeon,	2 5		1849 to 1852 inclusive.
Fort Richardson,	Post Surgeon,	1	- 9	1852, 1853 and 1856 to 1861 inclusive.
Fort Terrett,	Post Surgeon,	1	9	1852 and 1853.
Fort Worth,	Post Surgeon,	3	10	1849 to 1853 inclusive.
Franklin,	Post Surgeon,	i	7	1860 and 1865.
Gilmer,	J. M. Glasco,	1	9	1859 to 1861 and 1867 to 1869, both inclusive
Greenville.	Dr. R. De Jernett,	ô	7	1860.
Huntsville,	T. Gibbs,	0	2	1854 and 1856.
Jefferson,	W. T. Epperson,	Ŏ.	1	1859.
Kaufman,	James Brown and J. T.	1	3	1859 and 1866.
·	Rayal,			
Larissa,	F. L. Yoakum,	2	0	1858 and 1859.
Long Point,	M. Rutherford,	0	3	1867.
Mine Creek,	***************************************	1	0	1869.
Palestine,		-0	3	1869.
Phantom Hill,	Post Surgeon,	2	1	1851, 1852 and 1853.
Preston,	D 01	0	10	1859 and 1860.
Round Top,	Bruno Shuman,	1	4	1860 and 1861.
Springfield,	T. A. Turner,	0	1	1859.
Tarrant,	Dr. B. L. D'Spain and J.	0	11	1859 and 1860.
Turnaria Daint	M. Ewing,	0	9	1001
Turner's Point, Union Hill,	J. Rayal,	0	2	1861.
Waco,	Dr. W. H. Gantt, Edward Merrill, M.D.,	3 2	11 0	1857 to 1861 inclusive.
Washington,	B. H. Rucker,	3	10	1867, 1868 and 1869. 1856 to 1859 inclusive.
Webberville,	D. H. Rucker,	1	5	1859, 1860 and 1861.
Wheelock,		1	8	1859, 1860 and 1861.
				1000, 1000 and 1001.

¹ Observed at Garlandsville, Jackson, Marion, Paulding, P. H. Academies, Prairie Line, Vicksburg and Yazoo City.

2 From this table we obtain the following summary of results:-

	Spring.	Summer.	Autumn.	Winter.	The year.
Average velocity of all winds in miles per hour Velocity in mean direction, on the supposition that the winds	5.24	6.14	4.57	5.29	5.31
from every point of the compass move with the foregoing average velocity. True velocity in mean direction, giving to the winds from the several points of the compass each their own average velocity.	.73	1.87	1.18	.72	.50
as shown in the table above	$^{1.12}_{+.39}$	1.10 77	1.00 —.18	.95 +.23	+.03

Observed at Brook Haven, Columbia, Elliott Academy, Fayette, Kingston, Monticello, Natchez, Port Gibson,
 Salem High School, Washington and Westville.
 Computed from the resultants for the seasons.

(Nos. 103 to 106.) Alabama and Mississippi, south of latitude 31°.

(Nos. 153 to 167.) Atlantic Ocean and Madeira Islands.

Observed as follows, viz :-

At Funchal, Madeira, during the years 1826, 1827, and 1828; also six years, 1865 to 1870.

At sea, for an aggregate period of nearly eleven years and nine months, the observations being collected and classified, from the logs of numerous sailing vessels, at the United States Naval Observatory, under the direction of Capt. M. F. Maury, superintendent.

(Nos. 168 to 176(b).) Southern Algeria, Tripoli, and Northern Egypt.

Observed at the following places, viz .:--

Geryville and vicinity, Southern Algeria, by Messrs. Ferronnays, Gauverit and Merés, from October 23, 1856, to February 7, 1857, including the observations made by Dr. Merés during the last half of a journey from Oran to Geryville, extending, say, 100 miles north of the latter place.

Desert of Sahara, lat. 30° to 33° N., long. 0° to 1° W., by Dr. Paul Merés in January and February, 1857.

Gardeia, Tuggurt, and adjacent portions of the desert of Sahara, lat. 32° to 34¼° N., long. 2° to 7° E., by Dr. Paul Merés from March 7th to June 21, 1858.

Ghadamis, Desert of Sahara, by Rohlfs.

62 April, 1875,

(Nos. 168 to 176(b).) Southern Algeria, etc.—Continued.

Biskra, Southern Algeria, in the desert of Sahara, by E. Renou, during the years 1845-6-7-8-51-52 and 53.

City of Tripoli, for an aggregate period of 32 months in the years 1843 to 1846 inclusive, and 1855.

Alexandria, Egypt, during a period of three years, 1858 to 1861.

Cairo, Egypt, by Lefebvre, for 41 days, in February and March, 1839; by Destouches for seven years (date not given), and by Hubbard at Cairo, and on the road to Sucz for five days in the year 1857. Also for 5 years, 1857 to 1861, inclusive, by Caneval, J. Franz, Prof. Dr. Keyer, Dr. Lantner Bey, and Prof. Dr. Bilharz.

Ismalia, by Λ . Gepek, six times a day from June 1, 1866, to May 31, 1868, two years. Port Said, by Vabre, six times a day, from June 1, 1866, to May 31, 1868, two years. Rosetta, Egypt, by Hunter, for 71 days in November, 1777, and January and February, 1778.

(Nos. 179 to 184.)

Turkey in Asia.

Observed at the following places, viz. :-

Baqdad, Mesopotamia, during the year 1783.

Bahmdun, Mount Lebanon, Syria, by Rev. S. H. Calhoun, with some interruptions, from November, 1844, to September, 1845, inclusive.

Bassora, from February to June inclusive, in the year 1784.

Beirut, Syria, by Dr. De Forest, from September, 1842, to August, 1843, and from November, 1843, to March, 1844, both inclusive, and 80 days, the date of which is not preserved; also by another observer during the years 1846 to 1854, inclusive.

Damascus, Syria, by Dr. Joseph Dickerson and Frederick Hubbard, from May 27 to June 6, 1857. Jerusalem, Palestine, by Dr. McGowan, from May, 1846, to February, 1847, and from April to July, 1847, both inclusive, and by Dr. T. Chaplin for a period of 51 years, from 1863 to 1868, inclusive.

and 10 in March, 1844.

The following extract from a letter of Rev. J. F. Lanneau to the author will serve to give an idea of the

winds of Palestine generally:—
"There are, however, some general remarks which my long residence in Syria and the Holy Land enables me to make concerning the direction of the wind and other topics alluded to in your letter, and which may be of some interest to you.

"The whole of Palestine is intersected by a chain of hills, or small mountains, rising to an elevation of "The whole of Palestine is intersected by a chain of hills, or small mountains, rising to an elevation of nearly three thousand feet, and extending north and south nearly midway between the Mediterranean and the Jordan. On the sea coast the wind generally blows 'off the land,' or from the east or southeast during the night, and follows the sun as the day advances, toward the south, southwest and west, and, perhaps, one-third of the time continuing on to north and northwest, increasing toward sunset, and shortly after dying away to a calm, which lasts until about midnight, when the land breeze again commences. At Jerusalem, however, and in the hill country of Judea, the direction of the wind is almost always from the northwest during winter and summer, except when the Shileak, the Arabic term for the wind commonly known elsewhere as the Sirocco, or east wind, blows from the desert. So uniformly prevalent is the northwestern, that the olive trees in the interior, situated so as to feel its constant influence, are inclined toward the southeast, and their handless checked in their convoicts direction by its force as that in some cases three-fourths or more of them branches checked in their opposite direction by its force, so that, in some cases, three-fourths or more of them

are on that side, thus:

This is very strikingly noticed immediately around Jérusalem.

"And this leads me to an obvious answer to one of your questions, viz.: 'Are there any local influences that would affect the direction of the wind?' I have always thought the position of Jerusalem, and that whole region, with the immense evaporation from the Dead Sea, and the Arabian desert to the southeast of it, must be the physical cause of the northwest direction of the wind the greater portion of the year, while the deep

gorge in the mountains, extending all the way from the valley of Jehoshaphat and Hinnom to the Dead Sea, gorge in the mountains, extending all the way from the valley of Jehoslaphat and Hinnom to the Dead Sea, occasions a stronger current over the Holy City and the Mount of Olives. The Arabs have a saying, that Jerusalem is the most windy place in the world, the centre of the earth, and thus attracting all the wind there, etc. During the wind the southwest wind on the coast, and the northwest wind in the interior, generally accompany a rain, though occasionally there is a shower from the southeast. A north wind on the sea coast always drives away rain, but it is generally a very chilly and uncomfortable one, and is considered by the natives as unwholesome. The rainy season commences about the 1st or 15th of October, and continues until the middle of April. Sometimes a few showers fall in September and May.''

The following description of the winds of Palestine is taken from Dr. Wm. Smith's Bible Dictionary:—
"N.W. from the Autumnal Equinox to November 1st; west from November to February; east from February to June; and north from June to the Autumnal Equinox."

1 Sixteen of the W. and S. W. observations are marked "sea breeze" in the original record, and if these be

 $^\prime$ Sixteen of the W. and S. W. observations are marked "sea breeze" in the original record, and if these be rejected the resultant for the year is S. 87° 56 $^\prime$ W. .28.

² Computed from the resultants for the seasons.

³ Six of these observations were marked "sea breeze" in the original record, and if these be rejected the resultant for the winter is S. 50° 57′ W. .51.

(Nos. 189 to 193.)

China and Southern Japan.

Observed at the following places, viz. :-

Decima, Japan, during the years 1845 to 1848, and 1852 to 1855-7 years.

Nangasaki, Japan, during an aggregate period of $6\frac{1}{2}$ years, from 1848 to 1855.

Shanghae, China, by Dr. D. B. McCartee, from November, 1850, to October, 1852, inclusive; also for two years by another observer in the years 1867 to 1869.

Simoda, Japan, by officers attached to the expedition under command of Commodore Perry, for an aggregate period of 76 days.

Tinghai, China, by Champenois, from September, 1860, to February, 1861, inclusive.

ZONE No. 13.

Latitude 25° to 30° North.

The data for the study of the winds of this zone consist of observations made at over 115 stations on land, for an aggregate period of over 280 years; and at sea for about 23 years. The distribution is as follows:—

Where observed.	No. of Stations.	Aggregate length of time.
Pacific Ocean,		12 years 10 months.
Mexico,	10+	3 years 4 months.
United States,	64	217 years 11 months.
Atlantic Ocean,		nearly 10 years.
Islands of the Atlantic,	2	over 4 years 1 month.
Africa,	15	3 years 3 months.
Persian Gulf,		145 days.
Asia,	24	41 years.
Islands of the Pacific,	2	118 days.

(Nos. 1 to 5.) Pacific Ocean, east of longitude 180°.

Computed from observations for an aggregate period of about 13 years, collected and classified from the logs of numerous sailing vessels, at the United States Naval Observatory, under the direction of Capt. M. F. Maury, Superintendent.

(No. 59.)

Northern Bahamas.

Computed from observations made for an aggregate period of over four years, in the years 1841, 1842, 1843, 1845, 1858 and 1859. A part, and perhaps all, of them were made by A. M. Smith, at Nassau, on the island of New Providence.

Teneriffe, Canary Islands. (No. 71.)

Observed on board the brig Ocean during the month of December, 1820, partly while lying at anchor at Teneriffe, and partly between there and the Madeiras, as follows:-

North 14, N. E. 120, E. N. E. 60, East 122, S. E. 14, calm or variable 174.

Direction of resultant, N. 67° 34' E.

Ratio of resultant to sum of winds, including calms, .58.

(Nos. 71(a) to 75.) Sahara Desert, Egypt, and Mount Sinai.

Observed at the following places, viz. :-

Cassier, in Upper Egypt, by Lefebore, for five days in April, 1839.

Farafeh, Fayoum, Khargeh, Garah, Qasr (Cossier),

and the intervening deserts in Western Egypt, by Frederick Cailliaud, from November 12, 1819, to March 19, 1820.

Siwah, Zaboon,

Gournah, by Frederick Cailliand, from May 26 to July 14, 1820, except 4 days, and from July 1 to August 31, 1822, except 6 days.

Mount Sinai, by Dr. Joseph Dickinson, and Frederick Hubbard, from March 26 to April 20,

Mourzouk, Sahara, for six months, by Gerhard Rohlfs, date not known.

River Nile, between latitude 27° and 30°, from January 1 to 15, and from March 4 to 14; and between latitude 24° to 27° in Upper Egypt, from January 16 to 26, and from February 13 to March 4, all inclusive, and in the year 1857.

Suez, by officers of the Telegraph Station, for two years, from June 1, 1866, to May 31, 1868, six times a day, viz.: 6 A. M., 9 A. M., Noon, 3, 6, and 9 P. M.

(No. 76.)

Persian Gulf.

Computed from observations for an aggregate period of 145 days, collected and classified from the logs of different sailing vessels, at the United States Naval Observatory, under the direction of Capt. M. F. Maury, Superintendent, as follows, viz.:—

Spring, North 2, N. E. 1, East 2, S. E. 4, S. W. 4, W. S. W. 1, West 4, W. N. W. 2, N. W. 6, calm 2.

Direction of resultant N. 78° 29' W.

Ratio of resultant to sum of winds .30.

Number of days 28.

Autumn, East 10, E. S. E. 2, S. E. 1, S. S. E. 10, South 6, S. S. W. 3, S. W. 14, W. S. W. 8, West 5, W. N. W. 2, N. W. 10, N. N. W. 4, calm 3.

Direction of resultant S. 24° 11′ W.

Ratio of resultant to sum of winds .38.

Number of days 78.

Winter, East 4, S. E. 4, W. S. W. 3, West 8, W. N. W. 5, N. W. 5, N. N. W. 2, calm 2.

Direction of resultant N. 53° 19' W.

Ratio of resultant to sum of winds .39.

Number of days 39.

(Nos. 77 to 97.)

India.

Observed at the following places, viz .:-

Agra, during the years 1865 to 1869 inclusive.

Aimere, during the years 1869 and 1871.

Allahabad, during the year 1871.

Bareilly, during the years 1869 and 1871.

Benares, during the years 1864 to 1869 inclusive, and the year 1871, excepting the month of September.

Bhawulpoor, for the months of August and September, 1871.

Chuckrata, during the year 1869 and the months of October, November, and December, 1871.

Futtehourh, during the years 1869 and 1871.

Futtehpore and Patna, and along the river Gauges between these points, from May to December inclusive, in the year 1826.

Goruckpore, during the years 1869 and 1871.

Jahnsie, during the year 1869 and the first eleven months of 1871.

Lucknow, during the year 1869 and January, February, April, and October, 1871.

Meerut, during the years 1869 and 1871.

Mozufferepore, by T. Dashwood, from December, 1832, to February, 1833, inclusive.

Patna (see Futtehpore above).

Raneekhet, during the year 1871.

Roorkee, during the years 1864 to 1869 inclusive, and 1871.

Sukkur, from May to September inclusive, in the year 1844

ZONE No. 14.

LATITUDE 20° TO 25° NORTH.

The data for the study of the winds of this zone consist of observations made at over 36 stations on land, for an aggregate period of over 52 years; at sea for about 26 years. The distribution is as follows:—

Where observed.	No. of Stations.	Aggregate length of time.
Sandwich Islands,	3	2 years 9 months.
Mexico,	11	1 year 4 months.
Florida Keys and West Indies,	10	19 years 6 months.
Atlantic Ocean,		nearly 8 years.
Africa,	4	3 months.
Red Sea,		29 days.
Arabian Sea,		454 days = 1 year 3 months.
Asia,	8	28 years 7 months.
Bay of Bengal,		over 1 year.
China Sea,	1	nearly 2 years.
Pacific Ocean,		5000 days = 13 years 8 months.

(Nos. 1 to 6.) Sandwich Islands and the Pacific Ocean.

East of Longitude 180°.

Observed at the following places, viz .:-

At sea, for an aggregate period of about 13 years; the observations being collected and classified from the logs of numerous sailing vessels, at the United States Naval Observatory, under the direction of Captain M. F. Maury, superintendent.

Honolulu, for 406 days in the years 1837, 1840 to 1843 inclusive, and October, 1852, to January, 1853, inclusive.

Lahainoluna, during the months of May, June, and July, 1844.

Waioli, by Edward Johnson, from April, 1845, to March, 1846, inclusive.

ZONE No. 15.

LATITUDE 15° TO 20° NORTH.

The data for the study of the winds of this zone consist of observations made at over 26 stations on land, for an aggregate period of over 39 years: at sea for 26 years 3 months. The distribution is as follows:—

Where observed.	No. of Stations.	. Aggregate length of time.
Pacific Ocean, Mexico, West Indies, Atlantic Ocean, Bay of Bengal, China Sea, Africa, Asia.	10 5 8+	4074 days = 10 years 10 months. 4 years. 3 years. nearly 7 years. 1740 days = 4 years 8 months. 1350 days = 3 years 7 months. 1 year 4 months. 13 years 7 months.
Red Sea,		24 days.

(Nos. 1 to 5.) Pacific Ocean, east of longitude 180°.

Computed from observations for an aggregate period of 3451 days, collected and classified, from the logs of numerous sailing vessels, at the United States Naval Observatory, under the direction of Capt. M. F. Maury, Superintendent.

(Nos. 6 to 13.) Southern Mexico and Honduras.

Computed from observations made at the following places, viz. :-

City of Mexico, by Louis Berlandier, for 92 days in summer and 95 in autumn, during transient sojourns in the city, in the years 1819 to 1825, and by Prof. L. C. Ervendberg, during the first eleven months of 1856. The latter were reported to the Smithsonian Institution.

Cordova, by J. A. Hicto.

Frontera Tabasco.

Vera Cruz, by officers of the Medical Department of the United States Army from June, 1847, to August, 1848, inclusive, except February; and by an observer whose name is not preserved, from August to December inclusive in 1856, and during the months of May, 1857. The latter observer appends a note saying that "the winds recorded in the column headed N. W. were generally N. N. W.," and, therefore, in preparing the following table they were distributed equally between the column headed North and N. W.

Mazatlan, Mexico, 42 days in January and February, 1848.

Minatitlan, Mexico, 12 months in 1858 and 1859.

Mirador, Mexico, 12 months in 1858 and 1859.

San Juan Bautiste, Mexico, 12 months in 1858 and 1859.

Truxillo, Honduras, by E. Purdot, July to December inclusive, 1854.

ZONE No. 16.

LATITUDE 10° TO 15° NORTH.

The data for the study of the winds of this zone consist of observations made at over 22 stations on land, for an aggregate period of 46 years 1 month; and at sea for 26 years 5 months. The distribution is as follows:—

Where observed.	No. of Stations.	Aggregate length of time.
Pacific Ocean,		3254 days = 8 years 10 months
America,	5	3 years 3 months.
West Indies,	2	7 years 2 months.
Atlantic Ocean,		nearly 7 years.
Cape Verde Islands,	1 1	1 year 5 months.
Africa,	7	7 years 4 months.
Red and Arabian Seas,		over 2 years.
Asia,	5	20 years 5 months.
Bay of Bengal,		nearly 4 years 6 months
China Sea,		over 4 years.
Gulf of Siam,		34 days.
Islands of the Pacific,	2	6 years 6 months.

(Nos. 1 to 5.) Pacific Ocean, east of longitude 180°.

Computed from observations for an aggregate period of 2706 days, collected and classified, from the logs of the different sailing vessels, at the United States Naval Observatory, under the direction of Captain M. F. Maury, Superintendent.

(Nos. 1 to 5.)

(Nos. 7 to 12.) New Granada and Venezuela (northern parts of each).

Observed at the following places, viz. :-

Cartagena, New Granada, by Captain John Parsons, on board the ship Scorpion, from April 23 to June 11, 1854 inclusive, and published in No. 1 of the Meteorological Papers of the London Board of Trade.

Caraccas, Venezuela, by A. Avellado, during the year 1868.

Colonia Tovar, Venezuela, by Augustus Fendler, in the months of June, August, September and October, 1856. It seems probable that the record embraces only the exceptional surface winds, the predominant ones from easterly and northerly points being generally omitted. The record of the motion of the clouds is more complete.

Porto Cabello, Venezuela, by Mr. Litchfield, from June, 1843, to February, 1844, inclusive. 68 May, 1875.

(Nos. 7 to 12.) New Granada and Venezuela.—Continued.

(No. 25.)

District of Senaar, Southern Nubia.

Observed by Frederic Cailliand, from June 5, to December 21, 1821, and from February 19 to 28, 1822. All the observations were made at the city of Senaar, except during the first seven days, when they were made within a distance of 60 miles north of the city, and during twenty days of December and eight of February, when they were made at different points extending as far south as the southern limits of the district.

ZONE No. 17.

LATITUDE 5° TO 10° NORTH.

The data for the study of the winds of this zone consist of observations made at over 16 stations on land, for an aggregate period of 27 years; at sea for over 40 years 6 months. The distribution is as follows:-

Where observed.	No. of Stations.	Aggregate length of time.
Pacific Ocean,		4221 days = 11 years 6 months.
America,	11	13 years 9 months.
Atlantic Ocean,		over 9 years.
Africa,	3	5 years 3 months.
Indian Ocean,		over 16 years.
Cevlon,	3	8 years.
China Sea,		4 years.

Pacific Ocean, east of longitude 180°.

Computed from observations for an aggregate period of 3985 days, collected and classified from the logs of different sailing vessels, at the United States Naval Observatory, under the direction of Capt. M. F. Maury, Superintendent, as follows, viz.:-

(Nos. 38 to 41.)

Island of Ceylon, Indian Ocean.

Observed at the following places, viz.:-

Colombo, during a period of six years, from 1853 to 1859.

Point de Galle, during the year 1854.

Trincomalu, during the year 1854.

(Nos. 38 to 41.)

(Nos. 42 to 49.) Indian Ocean, China Sea and Pacific Ocean.

West of longitude 180°.

Indian Ocean, for an aggregate period of over six years.

China Sea, for an aggregate period of over four years.

Pacific Ocean, for an aggregate period of over four years.

From observations collected and classified, from the logs of numerous sailing vessels, at the United States Naval Observatory, under the direction of Capt. M. F. Maury, Superintendent.

ZONE No. 18.

LATITUDE 0° TO 5° NORTH.

The data for the study of the winds of this zone consist of observations made at 5 stations on land, for an aggregate period of over 10 years 5 months; at sea for about 62 years. The distribution is as follows:—

Pacific Ocean, South America, Atlantic Ocean, Africa, Indian Ocean, Asia, China Sea, Celebes Sea,	2 2 	14,291 days = 39 years 8 months. 9 years 1 month. over 8 years. 1 year 2 months. over 8 years 6 months. 2 months. 1003 days = 2 years 8 months. 1178 days = 3 years 2 months.

(Nos. 1 to 15.) Pacific Ocean, east of longitude 180°.

From observations made for an aggregate period of 38 years, collected and classified, from the logs of numerous sailing vessels, at the United States Naval Observatory, under the direction of Capt. M. F. Maury, Superintendent.

(No. 25.)

Cape Palmas, Liberia, Africa.

Observed from December 4, 1839, to January 31, 1840, as follows, viz.:—
December, South 30, S. S. W. 9, S. W. 24, W. S. W. 9, Calm 12.
Direction of resultant S. 26° 37′ W. (??)
Ratio of resultant to sum of winds .80.
January, N. E. 18, S. E. 3, South 9, S. W. 33, West 15, N. W. 6, Calm 9.
Direction of resultant S. 55° 43′ W. (??)
Ratio of resultant to sum of winds .36

(No. 25a.)

Central Africa.

Gondokoro and vicinity, latitude 4° 55' north, longitude 30° 48' east.

Observed by Lady Baker, from August 1, 1871, to July 7, 1873, during tours extending from 0° to 5° north latitude, and 31° to 33° east longitude.

In reference to the part of Lake Albert N'Yanza, lying between 1 and 2 degrees north latitude, Sir Samuel Baker says (1864): "The lake was calm every day till 1 P. M., when a southwest gale arose, and compelled the canoes to be hauled ashore."

SOUTHERN HEMISPHERE.

ZONES 19 TO 36.

Note.—In classifying the winds of the Southern Hemisphere the months of March, April and May have been designated *Spring;* June, July and August, *Summer;* September, October and November, *Autumn;* and December, January and February, *Winter*. On the maps the same notation and order have been preserved; the first season, Spring, being marked I; Summer, S; Autumn, A; and Winter, W.

ZONE No. 19.

LATITUDE 0° TO 5° SOUTH.

The data for the study of the winds of this zone consist of observations made at 4 regular stations on land, for an aggregate period of 24 years 7 months; at sea for about 73 years 3 months. The distribution is as follows:—

Where observed.	No. Stations.	Aggregate length of time.
Pacific Ocean, Atlantic Ocean, East Indies, Indian Ocean,	4	nearly 36 years. over 26 years. 24 years 7 months. 11 years 3 months.

(Nos. 1 to 19.) Pacific Ocean, east of longitude 180°.

From observations for an aggregate period of nearly 31 years, collected and classified, from the logs of numerous sailing vessels, at the United States Naval Observatory, under the direction of Capt. M. F. Maury, Superintendent.

ZONE No. 20.

LATITUDE 5° TO 10° SOUTH.

The data for the study of the winds of this zone consist of observations made at 4 stations on land, for an aggregate period of 9 years 10 months; and at sea for over 60 years 6 months. The distribution is as follows:—

Where observed.	No. of Stations.	Aggregate length of time.
Pacific Ocean,		over 19 years 6 months
Atlantic Ocean,		over 15 years.
Ascension Island,	1	2 years.
Indian Ocean,		over 26 years.
East Indies	3	7 years 10 months.

(Nos. 1 to 14.) Pacific Ocean, east of longitude 180°.

From observations for an aggregate period of over $15\frac{1}{2}$ years, collected and classified, from the logs of numerous sailing vessels, at the United States Naval Observatory, under the direction of Captain M. F. Maury, Superintendent.

ZONE No. 21.

LATITUDE 10° TO 15° SOUTH.

The data for the study of the winds of this zone consist of observations made at 2 stations on land, for an aggregate period of 2 years 8 months; at sea for over 54 years. The distribution is as follows:-

Where observed.	No. of Stations.	Aggregate length of time.
Pacific Ocean, Atlantic Ocean, South America, Indian Ocean, Australia,	1	nearly 16 years, over 17 years, 4 months, over 21 years, 2 years 4 months.

^{*} This form of presenting these observations—in a supplementary zone—was necessitated by their having been presented in groups extending both north and south of the parallel of 10° south latitude.

(Nos. 1 to 3.) Pacific Ocean, longitude 170° to 180° W.

From observations for an aggregate period of nearly 2 years, collected and classified, from the logs of numerous sailing vessels, at the United States Naval Observatory, under the direction of Capt. M. F. Maury, superintendent.

- Computed from the resultants for the sea:

(No. 14.)

Callao, Peru, South America

Computed from observations made by Commodore Wilkes, for 61 days, in the summer of 1839 and 1840, combined with those made by Charles Darwin, for 64 days, in April, June and July, 1844, as follows:—

Spring .- North 16, between south and east 138, south 22, between north and west 2.

Direction of resultant, S. 43° 16' E.??

Ratio of resultant to sum of winds .76.

Number of days, 30.

Summer.—North 98, between north and east 18, east 86, between south and east 1039, south $455\frac{1}{2}$, between south and west $193\frac{1}{2}$, west 80, between north and west 158. Calm or variable, 258.

Direction of resultant S. 24° 30' E.?

Ratio of resultant to sum of winds .51.

Number of days, 95.

(Nos. 15 to 29.)

Atlantic Ocean.

From observations for an aggregate period of over 17 years, collected and classified, from the logs of numerous sailing vessels, at the United States Naval Observatory, under the direction of Capt. M. F. Maury, Superintendent.

ZONE No. 22.

LATITUDE 15° TO 20° SOUTH.

The data for the study of the winds of this zone consist of observations made at 8 stations on land, for an aggregate period of 11 years 1 month; at sea for nearly 50 years. The distribution is as follows:—

Where observed.	No. of Stations.	Aggregate length of time.
Pacific Ocean,	1	about 10 years 6 months.
South America,	2	8 months.
Atlantic Ocean,	1	22 years 6 months.
St. Helena,	1	5 years
Mozambique Channel and Madagascar,	2	1 year.
Indian Ocean,	1	over 15 years 6 months.
Australia,	1	1 year 2 months.
Islands of the Pacific,	2	3 years 3 months.

(No. 1.) Feejee Islands, Pacific Ocean.

Computed from observations made under the direction of Commodore Wilkes, for 26 days, in spring, and 67 in summer, about the year 1840, as follows:—

Spring.—North 50, between north and east 10, east 31, between south and east 353, south 43, S. W. 3, west 3, N. W. 30, calm or variable 101.

Direction of resultant S. 50° 22' E.??

Ratio of resultant to sum of winds .54.

Summer.—North 23, between north and east 62, east 186, between south and east 820, south 120, between south and west 101, west 28, between north and west 89, calm or variable 179.

Direction of resultant S. 44° 33' E.?

Ratio of resultant to sum of winds .57.

(Nos. 2 to 6.) Pacific Ocean, longitude 150° to 180° W.

From observations for an aggregate period of 6 years, collected and classified, from the logs of numerous sailing vessels, at the United States Naval Observatory, under the direction of Capt. M. F. Maury, Superintendent.

Supplementary Zone.

(Intermediate between Zones 22 and 23.)

Coast of Brazil. Latitude 19° to 21° South.

The material for this zone does not belong exclusively either to the one that precedes or to the one that follows, the limit between the two being the parallel of latitude 20°. It is thought best, therefore, to arrange it in a zone by itself. It embraces an aggregate period of nearly 3 years, and was collected and classified at the United States Naval Observatory, under the direction of Capt. M. F. Maury, Superintendent.

(Nos. 51, 52, 53 and 54.)

ZONE No. 23.

LATITUDE 20° TO 25° SOUTH.

The data for the study of the winds of this zone consist of observations made at 4 stations on land, for an aggregate period of 19 years 4 months; and at sea for over 65 years. The distribution is as follows:—

Where observed.	No. of Stations.	Aggregate length of time.
Pacific Ocean, South America, Atlantic Ocean, Indian Ocean and Mozambique Channel, Isles Bourbon and Mauritius, New Caledonia,	2 1	over 12 years 3 months. 5 months. 24 years. over 28 years 6 months. 14 years. 4 years 11 months.

⁷⁴ June, 1875.

Pacific Ocean, east of longitude 180°. (Nos. 1 to 17.)

From observations for an aggregate period of over 11 years, collected and classified, from the logs of numerous sailing vessels, at the United States Naval Observatory, under the direction of Captain M. F. Maury, Superintendent.

¹ Computed from the resultants for the seasons.

² These apparent deflections from long, 70° to long, 120° W. are due, perhaps, less to monsoon influences, properly so called, than to difference of distance from the South American coast; the mean resultant for the year with which those for these seasons are all compared being that for the entire area included between the meridians just named.

(No. 18.)

Rio Janeiro, Brazil.

Computed from observations made by Charles Darwin for 68 days, in 1832, by Commodore Wilkes for 46 days, in 1838 and 1839, and by Burmeister for 48 days, in 1850.

Time of the year.	North.	N. E. or bet. N.& E.	East.	S. E. or bet, S. & E.	South.	S. W. or bet. S.& W.	West.	N. W. or bet. N.& W.	Calm or var,	Direction of resultant.	Ratio of resultant to sum of winds.

(Nos. 40 to 43.)

Isle of Bourbon1 and Mauritius.1

Observed at the following places, viz .:-

Port Louis, Mauritius, by Charles Meldrum, during a period of 11 years-1853 to 1859 and 1861 to 1865 inclusive.

- St. Dennis, Bourbon, during one year, date not preserved.
- St. Paul, Bourbon, during one year, date not preserved.
- St. Peter, Bourbon, during one year, date not preserved.

¹ Iu a paper on the Meteorology of Bourbon, by Mailland, published in the Annuaire de la Société Méteoro-In a paper on the meteorology of Bourbon, by Mailland, published in the Annuaire de la Societe Meteoro-logique of France, for January, 1862, he intimates that the observations at St. Paul should be rejected on account of its local position on the leeward side of the island; and remarks, in regard to Port Louis, that its position on the island of Mauritius is precisely similar to that of St. Paul on the Isle of Bourbon, and that, therefore, it would be an error to judge of the meteorology of the whole island from observations made at Port Louis. Bourbon is a volcanic island, of elliptical form, 38 miles long and 28 wide, and is traversed from north to south by a chain of mountains that rise at some points to the height of near 10,000 feet. The interior

of Mauritius is mountainous, but the mountains are not so high.

For the first six years only. Mr. Meldrum's observations for the last nwe years are as follows, viz.:—
North 69 East 1280 South 39 West 111 Variable 98

N. N. E. 47 E. S. E. 1803 S. S. W. 25 W. N. W. 176 Calm 1076

South 39 S. S. W. 25 S. W. 32 W. S. W. 62 West 111 W. N. W. 176 N. W. 149 N. N. W. 109 E. N. E. 494 S.S.E. 454

Hence the direction of the resultant for this latter series is about E. S. E., and its ratio to the sum of the winds about .53, scarcely differing from the series computed above.

(Nos. 44 to 53.) Indian Ocean, longitude 55° to 115° east.

From observations for an aggregate period of over 20 years, collected and classified, from the logs of numerous sailing vessels, at the United States Naval Observatory, under the direction of Capt. M. F. Maury, Superintendent.

ZONE No. 24.

LATITUDE 25° TO 30° SOUTH.

The data for the study of the winds of this zone consist of observations made at 5 stations on land, for an aggregate period of 5 years 3 months; at sea for over 61 years. The distribution is as follows:—

Where observed.	No. Stations.	Aggregate length of time.
Pacific Ocean, South America, Atlantic Ocean, Africa, Indian Ocean, Australia,	2 1 2	12 years 6 months. 11 months. 18 years 6 months. 2 years. over 30 years. 2 years 4 months.

(Nos. 1 to 21.)

Pacific Ocean, east of longitude 180°.

From observations for an aggregate period of 10 years, collected and classified, from the logs of numerous sailing vessels, at the United States Naval Observatory, under the direction of Capt. M. F. Maury, Superintendent.

¹ Computed from the resultants for the seasons.

² These apparent deflections from longitude 70° to longitude 120° W. are due, perhaps, less to monsoon influences, properly so called, than to difference of distance from the South American coast; the mean resultant for the year with which those for these seasons are all compared being that for the entire area included between the meridians just named.

(Nos. 23 and 24.) Northern Chili and Southern Paraguay, South America.

Observed at the following places, viz :-

Chanacillo, Chili, from November, 1858, to March, 1859, inclusive.

Assumption, Paraguay, by E. A. Hopkins, from March to August, inclusive, in the year 1854, and reported to the Smithsonian Institution.

ZONE No. 25.

LATITUDE 30° TO 35° SOUTH.

The data for the study of the winds of this zone consist of observations made at 14 stations on land, for an aggregate period of 47 years 9 months; at sea for over 70 years. The distribution is as follows:—

Where observed.	No. of Stations.	Aggregate length of time.
Pacific Ocean, South America, Atlantic Ocean, Africa, Indian Ocean, Australia,	7 3 	over 31 years. 7 years 9 months. over 14 years. 25 years 6 months. nearly 25 years. 14 years 6 months.

(Nos. 1 to 19.) Pacific Ocean, east of longitude 180°.

From observations for an aggregate period of nearly $25\frac{1}{3}$ years, collected and classified, from the logs of numerous sailing vessels, at the United States Naval Observatory, under the direction of Capt. M. F. Maury, superintendent.

Australia.

Observed at the following places, viz.:-

Adelaide, South Australia, during the years 1859 to 1863 inclusive.

Buchsfelde, South Australia, by O. Schomburg, from January 1850, to June 1851, inclusive.

Freemantle, West Australia, during the years 1854 and 1855.

Sidney, New South Wales, at the Observatory, by W. Scott and George R. Smalley, during the years 1860 to 1863 inclusive, 1867 and 1868.

ZONE No. 26.

LATITUDE 35° TO 40° SOUTH.

The data for the study of the winds of this zone consist of observations made at 19 stations on land, for an aggregate period of about 64 years; at sea for about 95 years 6 months. The distribution is as follows:—

Where observed.	No. of Stations.	Aggregate length of time.
Pacific Ocean, Atlantic Ocean, Indian Ocean, Australia, New Zealand,	14 5	nearly 20 years. 21 years 6 months. over 54 years. 31 years 4 months. about 33 years.

(Nos. 1 to 26.)

Pacific Ocean, east of longitude 180°.

From observations for an aggregate period of nearly 17 years, collected and classified, from the logs of numerous sailing vessels, at the United States Naval Observatory, under the direction of Captain M. F. Maury, Superintendent.

(Nos. 88 to 90(a).)

Northern New Zealand.

Observed at the following places, viz :-

Aukland, at station of Royal Engineers, during the years of 1853 to 1859 inclusive, 1866 and 1867.

Bay of Islands, under direction of Commodore Wilkes, for seven days, in the spring of 1840.

Mongonui, 1857 to 1869(?), probably by government officers.

. Russel, by L. Williams, from April 24th, 1843, to February 10th, 1844.

Taranaki, 1857 to 1869(?), probably by officers of the government.

ZONE No. 27.

LATITUDE 40° TO 45° SOUTH.

The data for the study of the winds of this zone consist of observations made at 10 stations on land, for an aggregate period of 37 years 6 months; at sea for over 52 years. The distribution is as follows:—

Where observed.	No. Stations.	Aggregate length of time.
Pacific Ocean,	1	over 21 years 6 months.
South America,	3	5 years 9 months.
Atlantic Ocean,		over 8 years.
Indian Ocean,		over 22 years 6 months.
Van Dieman's Land,	3	20 years 9 months.
New Zealand,	4	11 years.

(Nos. 1 to 17.) Pacific Ocean, east of longitude 180°.

From observations for an aggregate period of over $17\frac{1}{2}$ years, collected and classified, from the logs of numerous sailing vessels, at the United States Naval Observatory, under the direction of Capt. M. F. Maury, Superintendent.

Van Dieman's Land (Tasmania).

Observed at the following places, viz. :-

Hobart Town, by Francis Abbot, at his private observatory, during the years 1857 to 1865 inclusive.

Kent's Group, for a period of five years, 1861 to 1866.

Port Arthur, for a period of five years, 1861 to 1866, and also for an aggregate period of 666 days, by Lempriere, in the years 1837, 1838 and 1839.

ZONE No. 28.

Latitude 45° to 50° South.

The data for the study of the winds of this zone consist of observations made at 3 stations on land, for an aggregate period of 14 years 6 months; and at sea for 27 years, 6 months. The distribution is as follows:—

Where observed.	No. of Stations.	Aggregate length of time.	_
Pacific Ocean, Atlantic Ocean, Indian Ocean, Desolation Island, New Zealand,	1 2	nearly 19 years. 4 years. 4 years, 6 months. 2 years. 12 years 6 months.	

(Nos. 1 to 24.) Pacific Ocean, east of longitude 180° from Greenwich.

From observations for an aggregate period of nearly 12 years, collected and classified, from the logs of numerous sailing vessels, at the United States Naval Observatory, under the direction of Capt. M. F. Maury, Superintendent.

ZONE No. 29.

Latitude 50° to 55° South.

The data for the study of the winds of this zone consist of observations made at 3 stations on land, for an aggregate period of nearly 12 years 8 months; at sea for 17 years 3 months. The distribution is as follows:—

Where observed.	No. of Stations.	Aggregate length of time.
Pacific Ocean,	1	9 years 6 months.
South America and adjacent islands.	2	8 years 8 months.
Atlantic Ocean,		7 years 6 months.
Antarctic Ocean,	1	3 months.
Heard's Island,	1	nearly 4 years.

(Nos. 1 to 26.) Pacific Ocean, east of longitude 180° from Greenwich.

From observations for an aggregate period of over $9\frac{1}{2}$ years, collected and classified from the logs of numerous sailing vessels, at the United States Naval Observatory, under the direction of Captain M. F. Maury, Superintendent.

(Nos. 50 to 56.) Antarctic Ocean and Heard's Island.

Observed as follows, viz. :-

At Heard's Island, by officers of whale ships from New London, Connecticut, for an aggregate period of nearly four years, in the years 1856 to 1859 inclusive.

At Sea, for an aggregate period of 83 days, by Capt. Cook, New London whalers and others. The observations of most of the latter were collected and classified at the United States Naval Observatory.

Zone intermediate between 29 and 30.

Latitude 54° to 56° South.

The material for this zone does not belong exclusively either to the one that precedes or to the one that follows, the limit between the two being the parallel of latitude 55°. It is thought best, therefore, to arrange it in a zone by itself.

(Nos. 1 to 16.) Off Cape Horn, longitude 55° to 89° west.

From observations for an aggregate period of over $6\frac{1}{2}$ years, collected and classified, from the logs of numerous sailing vessels, at the United States Naval Observatory, under the direction of Capt. M. F. Maury, Superintendent.

ZONE No. 30.

LATITUDE 55° TO 60° SOUTH.

The data for the study of the winds of this zone consist of observations made at 2 stations on land, for an aggregate period of 6 months; at sea for 14 years 6 months. The distribution is as follows:—

Where observed.	No. of Stations:	Aggregate length of time.
Antarctic Ocean, Terra del Fuego,	2	over 14 years 6 months. 6 months.

(Nos. 1 to 26.) Antarctic Ocean, longitude 67° west to 180°.

From observations for an aggregate period of $9\frac{1}{2}$ years, collected and classified, from the logs of numerous sailing vessels, at the United States Naval Observatory, under the direction of Capt. M. F. Maury, Superintendent.

(No. 27.) Orange Bay and vicinity, Terra del Fuego.

Computed from observations made hourly, under the direction of Commodore Wilkes, from February 18th, to April 20th, 1839, together with those for three days, collected and classified at the United States Naval Observatory, as follows:—

Spring.—North 46, N. E. 61, East 9, S. E. 21, South 17, S. W. 678, West 120, N. W. 84, N. N. W. 12; calm 194.

Direction of resultant S. 59° 29' W.?

Ratio of resultant to sum of winds .56.

Number of days 54.

Winter.—North 9, N. E. 16, East 10, S. W. 156, West 7, N. W. 11; calm 55.

Direction of resultant S. 51° 36' W.??

Ratio of resultant to sum of winds .50.

Number of days 11.

(No. 28.) Saint Martin's Cove and vicinity, Terra del Fuego.

Computed from observations collected and classified at the United States Naval Observatory, for an aggregate period of 36 days, combined with those made by Charles Darwin, for 7 days, in the winter of 1832, and those made by Sir James Ross, for 71 days, in the autumns of 1842 and 1843, as follows:—

Autumn.—North 3, N. E. 3, E. N. E. 8, East 2, S. E. 1, South 2, S. S. W. 9, S. W. 69, W. S. W. 11, West 18, W. N. W. 8, N. W. 11, N. N. W. 10; calm 12.

Direction of resultant S. 67° 41' W.?

Ratio of resultant to sum of winds .57.

Number of days 95.

Winter.—N. N. E. 1, N. E. 2, South 4, S. S. W. 3, S. W. 2, W. S. W. 4, West 2, W. N. W. 3, N. W. 1.

Direction of resultant S. 60° 59' W.?

Ratio of resultant to sum of winds .52.

Number of days 19.

(Nos. 29 to 46.) Antarctic Ocean, longitude 73° west, eastwardly to 180°.

From observations for an aggregate period of over 5 years, collected and classified, from the logs of numerous sailing vessels, at the United States Naval Observatory, under the direction of Capt. M. F. Maury, Superintendent.

ZONE No. 31.

Latitude 60° to 65° South.

The data for the study of the winds of this zone consist of observations made on the Antarctic Ocean for an aggregate period of 505 days.

80 July, 1875,

(Nos. 1 to 12.)

Antarctic Ocean.

.Observed for an aggregate period of 505 days, as described in the following table and notes appended :-

⁶ Computed from observations made by Sir James Ross, in the winter of 1842-3.

ZONE No. 33.

LATITUDE 70° TO 75° SOUTH.

The material for the study of the winds of this zone is derived from the observations of the Antarctic explorers, Captain Cook and Sir James Ross, for an aggregate period of 41 days.

(No. 1.) Antarctic Ocean, longitude 106° to 108° west.

Computed from observations made by Captain Cook, for two days, in the winter of 1773-4, as follows:—

North 1. East 1.

Direction of resultant N. 45° E.???

Ratio of resultant to sum of winds .71.

(No. 2.) Antarctic Ocean, longitude 15° to 18° west.

Computed from observations made by Sir James Ross, for four days, in the spring of 1841, as follows:—

N. E. 3. East 1.

Direction of resultant N. 55° 48' E.???

Ratio of resultant to sum of winds .94.

(No. 3.) Antarctic Ocean, longitude 166° to 176° east.

Computed from observations made by Sir James Ross, for 35 days, in the winter of 1840-41, as follows:— *

North 3, N. E. 4, E. N. E. 2, East 9, E. S. E. 4, S. E. 14, S. S. E. 4, South 4, S. S. W. 1, S. W. 4, W. S. W. 6, West 4, W. N. W. 2, N. W. 2, N. N. W. 1; calm 4

Direction of resultant S. 38° 42' E.?

Ratio of resultant to sum of winds .29.

ZONE No. 34.

LATITUDE 75° TO 80° SOUTH.

Sir James Ross appears to be the only explorer who ever penetrated this zone, and the material for the study of its winds is therefore confined to his observations, which were made for a period of 34 days, in the winter of 1840-1, between the meridians of longitude 166° and 168° east from Greenwich, as follows:—

North 2, N. N. E. 6, N. E. 9, E. N. E. 2, East 13, E. S. E. 4, S. E. 6, S. S. E. 4, South 3, S. S. W. 2, S. W. 6, W. S. W. 2, West 1, N. W. 6; calm 2.

Direction of resultant N. 88° 41' E.

Ratio of resultant to sum of winds .31.

ZONES Nos. 35 and 36.

LATITUDE 80° TO 90° SOUTH.

These zones have never been visited by man, and the character of the winds that blow over them is very much a matter of conjecture. From the analogy of the northern hemisphere, as well as from theory, we may suppose that they blow from some southerly point, and become more easterly as they advance. And this view is confirmed by the fact shown above that every computed resultant south of latitude 65° is easterly.

WINDS OF THE GLOBE.

SERIES C. VELOCITY TABLES AND DEFLECTING FORCES.

VELOCITY TABLES.

THESE tables, and the accompanying Plates 13 and 25, are designed to elucidate the last of the series of questions proposed at the outset of this discussion, and to show the effect of combining the element of force or velocity, with that of time, in computing the mean direction of the wind. The question itself is a highly important one, for since the real point that we wish to arrive at is the mean direction and amount of the actual motion, or transfer, of the air that passes over any given place, it is obvious that if there is a difference in the velocity of winds from the different points of the compass, or over different sections of country, such as to materially affect the results that would be obtained if it were always and everywhere the same, all the computations in the foregoing pages must require correction, if they be not rendered in great measure worthless; for (where not expressly stated to the contrary) they were all made on the assumption that the velocity was uniform; or, which is the same thing, without any reference to the velocity. And, not only so, but nearly all the observations that have ever been taken, both by land and sea, must be thrown aside (for in very few of them has the velocity of the wind been attempted to be recorded), and the whole work of observation must be commenced anew.

This question can be determined only by observation and experiment. We can know nothing about it à priori. Difference of velocity may produce a very great effect upon the mean direction, or very little, or none all. The solution of this question must therefore be viewed as vital to the search for the laws of atmospheric circulation.

The accompanying tables, collected from Series B of this work, are designed to give a synoptical view of the elements on which a determination may be based, as derived from observations taken mainly in the United States by the observers that reported to the Smithsonian Institution, in the years 1854, 1855, 1856 and 1857. The laborious work required to obtain the results here presented, was performed, under the direction of the author, by his brother, Robert A. Coffin, A.M., of Conway, Massachusetts, and other assistants, the cost being defrayed by the

Smithsonian Institution.¹ Few of the observers possessing anemometers, the velocities were usually estimated in force numbers, which were reduced to miles per hour on the following scale:—

1.	Very light bre	eeze .					2	miles	per	hour
	Gentle breeze								4.4	44
3.	Fresh breeze .						12	4.4	66	66
4.	Strong wind .		u				25	4.4	64	16
5.	High wind .						35	"	"	44
6.	Gale						45	66	66	44
7.	Strong gale .						60	4.6	4.6	6.6
8.	Violent gale .						75	4.4	4.6	67
9.	Hurricane .						90	4.6	4.6	46
10.	Most violent h	nurricane					100	44	6.6	44

¹ [From a monograph found among my father's unpublished writings, I extract the following statement in reference to these Velocity Tables, which were then incomplete, being in course of computation.—SELDEN J. COFFIN.]

"In the Winds of the Northern Hemisphere, 1853, this question was discussed, so far as the comparatively meagre data then at my command allowed, and the conclusion arrived at was, that, as a general thing, this difference of velocity, while it increases the magnitude of the resultant, does not appreciably affect its direction. The data on this continent from which I reached the above conclusion, consisted of observations taken at 103 different places, for an aggregate period of 397 months, or about 33 years, more than half of them being from Eastern and Middle States, and only an aggregate of about two years from States and Territories west of Ohio.

"In 1857, the Secretary of the Smithsonian Institution ordered a thorough and exhaustive discussion of the subject, based on the observations reported to the Institution for the years 1854-7, from 418 different places on this continent, for an aggregate period of 8589 months, or over 700 years, in which each observer noted the direction of the wind, usually three times a day, and affixed to each record a number from 0 to 10 to represent the velocity, according to the scale given above, based on the experiments of Rouse and Smeaton.

"The method of discussion was, first to group the places of observation into districts of moderate geographical extent, then to compute, for each district, the mean velocity of the winds, as estimated by the observers, both the lower current and that indicated by the motion of the clouds, for each of the eight principal points of the compass, for each season of the year, and for the whole year, counting all winds between the N. and E. points as northeast, those between S. and E. as southeast, etc., and finally to compute the resultant motion of each of the two currents, over each district, for each season of the year and the whole year, first from the actual motion estimated as above, and then, for the purpose of comparison, on the supposition that the winds from all directions moved with the same mean velocity. To carry out this plan required great labor, inasmuch as beside classifying the winds according to the points of the compass from which they came, the record of the estimated velocity at each separate observation, amounting in the aggregate to over three-fourths of a million, had to be translated into linear distance, or miles per hour. An aggregate of over 5 years of working time has been spent upon it. The work of classification was performed chiefly by ladies; that of translating into miles, which required only care and accuracy in applying the scale and summing up the results, by men competent for such work; while the trigonometrical resultants were mostly computed by Robert A. Coffin.

"The results corroborate the views advanced in The Winds of the Northern Hemisphere in regard to the magnitude of the resultants, but not in regard to their direction, both of which facts will appear from the following general statements, in which it will be seen that the effect of difference in velocity is to throw the resultant northerly far more frequently than southerly, and at a much greater angle; that it increases its magnitude far more frequently than it diminishes it, and by a greater amount.

[&]quot;In 10 districts north of the 45th parallel of latitude it is thrown northerly; in 9 at an average

Column I contains the name of the place of observation, to which is prefixed the zone and serial number, by reference to which on the preceding pages the reader can find the average velocity of the wind from each point of the compass for each of the seasons. See, for example, Red River Settlement; near the foot of page 148 we find, "Mean velocity in miles per hour, Spring, North 5.32, N. E. 2.71," etc. The places are also grouped—not as by the author, in strict sequence of latitude and longitude—but to conform as nearly as practicable to the divisions of the United States made in the "Discussion and Analysis of Winds."

Column II was computed as in all the tables of Series B, by having regard only to the number of observations, without any reference to velocity.

angle of 17° 32'; and southerly in one at an angle of 8° 38', making the average of the whole northerly by 15° 13'; while it increases the magnitude of the resultant in 5 of the districts by an average of 50 per cent., and diminishes it in 5 by an average of 15 per cent., making for the whole an average increase of 18 per cent.

"In 44 districts between the 40th and 45th parallels (exclusive of Great Salt Lake City where the results are too anomalous to be incorporated with the others), the resultant is thrown northerly in 36 at an average angle of 15° 49′, and southerly in 8 at an average angle of 4° 31′, making the average for the whole northerly by 12° 8′. The influence on the direction seems generally to be much greater in the western than in the eastern States of this belt, and this accounts for my failure to detect it when I prepared my former publication. The magnitude of the resultant is increased in 36 by an average of 29 per cent., and diminished in 8 by an average of 14 per cent., making for the whole an average increase of 21 per cent. In 20 districts between the parallels of 36½° and 40° the resultant is thrown northerly in 17 at an average angle of 16° 36′, and southerly in 3 at an average angle of 4° 11′, making the average for the whole northerly by 13° 29′, while its magnitude is increased in 19 districts by an average of 43 per cent., and diminished in but one, and that only by 11 per cent., making for the whole an average increase of 36 per cent.

"The near coincidence of the results in these three belts authorizes us to combine them, and we thus find that the mean influence from the parallel of 50° down to that of $36\frac{1}{2}^{\circ}$ is to render the resultant more northerly by about 13°, and to increase its magnitude about 25 per cent. This difference is not great, but may affect the general principle.

"Through the States of Tennessee and North Carolina, from latitude 35° to $36\frac{1}{2}$ °, the resultant is thrown northerly in 4 districts at an average angle of 18° 5′, and southerly in one at an angle of 33° 57′, the average for the whole being 7° 41′ northerly. Most of the observations in the latter district were taken at Knoxville, Tenn., where there may be some local cause that renders the south and southwest winds so much stronger than those from the north and northwest. In each of the 5 districts the magnitude of the resultant is increased, the average increase for the whole being 40 per cent. Notice the accumulating increase of the magnitude of the resultants as we pass southerly through the 4 belts above described, viz., 18, 21, 36 and 40.

"The results in the next belt extending from latitude 30° to 35° seem perfectly chaotic. In 7 out of 16 districts the resultants are thrown northerly at angles ranging from 1° to 126°, and in 9 southerly with nearly as wide a range, the average for the whole being 3° 23′ northerly. The magnitude of the resultants is increased in 7 districts and diminished in 9, the average being an increase of 2½ per cent. It is within this belt that the system of westerly winds breaks up and is replaced, as we go south, by the trade wind system, and the slight degree of prevalence of the wind in any direction allows it to be controlled very much by local influences.

"Still further south out of 6 districts represented, at 5 the resultant is thrown northerly at an average angle of 17° 48'. The remaining district is represented by the City of Mexico, where the general results are in some degree anomalous, and make a longer period of observation desirable In 5 of these districts the magnitude of the resultant is increased by an average of 25 per cent., while in one it is diminished by 8 per cent. The average increase for the whole being $19\frac{1}{2}$ per cent."

Column III is the laborious product obtained by computing the resultants from the number of miles travelled by the winds from each point of the compass for each season. As, for example, Red River Settlement, page 148, "Number of miles, Spring, North, 383, N. E. 38," etc. It therefore represents time multiplied by velocity.

The remaining columns IV, V, VI and VII, are taken from the sub-tables. (See, for instance, foot-note 2 on page 148.) Column IV containing the average velocity of all winds in miles per hour, though derived from the same source as the "Mean Velocity" for the separate points of the compass, is, of course, not the arithmetical average of the latter, but was separately computed. The numbers in column V show the velocity in miles per hour in the mean direction, on the supposition that the winds from every point of the compass move with the average velocity given in column IV. These figures are obtained by multiplying the numbers in column IV by the ratios in column II. Column VI exhibits the true velocity in the mean direction, giving to the winds from the several points of the compass each their own average velocity. The results are the product of the miles per hour in column IV multiplied by the corresponding ratios in column III. Column VII represents the excess of the velocities in column VI over those in column V, as expressed by the use of the plus sign, the minus sign being employed when the figures in column V are the greater. The "Mean Resultants" for the groups of stations in columns II and III were obtained mechanically by the use of a drafting instrument, and are given to the nearest whole degree, the fractions of a degree having been excluded after the computations were made.

A DRAFT OF THESE RESULTS is found in Plate 25, where the figures in column II are drawn as arrows, flying with the wind, the length of the shaft (without the barb) being proportioned to the ratios; those in column III are similarly noted, the barb being omitted, and the greater length of the shaft conforming to the increase in the ratios over those in column II. The average velocities given in column IV are found in the vertical series in the middle of the plate, a scale of miles being attached at the left. The vertical series at the extreme right-hand of the plate contains delineations of the results in the remaining columns; column V being shown in a dotted line, column VI in a continuous line; and the intervening space, which is in most cases filled with the sign +, representing column VII. In the individual stations at the lower part of the page, the velocities were, in some cases, so great as to need changes in the scale employed, which is, therefore, recorded in the margin.

An inspection of the tables and plate shows clearly that, as a general thing, the difference in the velocity of the winds from different points of the compass affects the resultant but slightly either in direction or amount. In the United States, north of 32° N. latitude, the resultant had by noting the actual velocities (i. e., the dotted arrow) is found inclined more to the right hand, that is, it represents a direction more northerly than the unbroken arrow that represents the effect when the velocity is disregarded. The annual resultants in the former case averaging S. 89°+ W. with a ratio of .261, and in the latter S. 80°+ W. .227. The divergence of these

two classes of annual resultants is therefore about nine degrees (8° 48 by one mode of reckoning and 9° 38 by another), the divergence being greatest in winter. In passing into the adjacent geographical zones, it is significant that, within the limits of the Polar and Equatorial systems of winds, the places represented on the chart with like uniformity exhibit divergence, but in the contrary direction, *i. e.*, the dotted arrow for velocity, is at the left hand of the continuous arrow for time.

The average velocity of all winds in the United States differs little from 7 miles an hour, being slightly in excess in the northeastern part of the Union, and less in the States nearer the centre of the continent. The anemometer gives greater figures than those obtained by estimation. The velocity in the mean direction on the hypothesis that the winds from every point of the compass move with an average velocity (given in column IV) is 1.7 miles per hour. But the true velocity in the mean direction, when each wind is allowed its own separate velocity, is nearly 2.0 miles per hour.

¹ In the "Winds of the Northern Hemisphere" the average hourly velocity of all winds was given as 5.8 miles; and the mean resultant obtained from the actual distances was stated to be S. 87° 44′ W 1.74 miles per hour; and that obtained by disregarding velocity S. 85° 59′ W. 1.53 miles per hour.

FORCES THAT DEFLECT THE CLOUD CURRENT OF THE ATMOSPHERE FROM ITS MEAN ANNUAL DIRECTION

The annual direction of the upper current, as indicated by the motion of the clouds, shows—in the temperate zone—a great uniformity from the west. Of the resultants given in the following table four-fifths are from points between west by north and southwest. If those stations that lie within the limits of the polar and equatorial systems of winds are excluded, the uniformity is almost without an exception. The ratio, 42 per cent., is nearly double that of the surface current (23 per cent.), thus showing a steadiness of motion admitting of little monsoon influence. Accordingly we find, in the right-hand columns of the following table, that the deflecting forces are usually quite small; in fact, so small that a map constructed on the same plan and scale as Plates 10, 11 and 12, would not satisfactorily exhibit their direction or amount. For this reason they are collected in the accompanying table. The yearly resultants are prefixed for ready comparison.

DISCUSSION AND ANALYSIS

OF

PROFESSOR COFFIN'S TABLES AND CHARTS

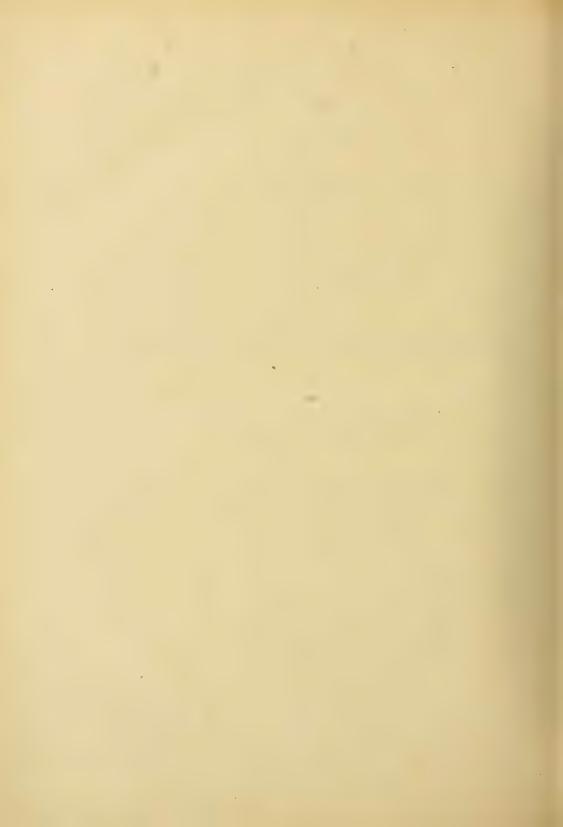

OF THE

WINDS OF THE GLOBE.

BY

DR. ALEXANDER WOEIKOF,
OF THE IMPERIAL GEOGRAPHICAL SOCIETY OF RUSSIA.

(657)

DISCUSSION AND ANALYSIS OF WINDS.

THE aim of Prof. Coffin in this work on the "Winds of the Globe," the reason why he did not write the text, and how I came to take charge of this part of it, has been already explained in the preface.

In what way the ideas of the deceased author would have been modified by the progress of theoretical meteorology in the last twenty years, as well as by the much more extended knowledge of facts we possess now, it is impossible to say. It is very likely, however, that he would have continued to rely principally on the inductive method, would have avoided hasty generalizations, and would have shown the same caution and candor as in his other works, omitting explanations of what our present knowledge did not give sufficient data, rather than mislead his readers.

Before drawing the conclusions which seem to follow from the tables and maps of this work, some explanations are necessary.

The object of this work is to ascertain the movement of the air over different parts of the earth's surface. For this purpose the mean direction and rate of progress of the wind were calculated according to the formula of Lambert. It is easy to see that to accomplish this with precision, we should know the velocity of the wind at all places at which calculations are to be made. Now we know the velocity of the winds in a somewhat accurate manner only for a very small number of stations. For many more the velocity of the wind was merely estimated, and for a majority of places, the direction of the wind alone is known. Now the progressive movement of the air over a certain place, even taking into account the direction only, without considering the number of miles travelled, can be ascertained from the number of observations alone if we make the supposition that all winds have the same velocity; but this is obviously not the case. In nearly all known instances where the velocity of the winds has been ascertained, it has been found to vary considerably; generally, the more accurate observations with self-registering anemometers give a greater difference between the velocities belonging to different directions of the winds than mere estimates have given, the difference being seldom less than 1 to 2, and sometimes even 1 to 4 or 1 to 5.

In considering attentively the observations for the stations where the number of observations, for hours, and the velocity are given, it is seen that generally the most frequent wind is also the strongest, or, comparing the mean direction of the wind calculated from the number of observations only, with that obtained by

taking into account the velocity of the winds, it will be found that in the last case the mean direction generally approaches nearer to the actual direction of the prevailing wind.

Besides it is seen that generally the ratio of resultant is greater in the second case than in the first.

Thus it follows that, when we have the mean direction of the wind at a given place, calculated from the number of observations only, we may infer that, if the velocity was known, it would modify the result in so far as to make the mean direction nearer to that of the prevailing wind, and the ratio of resultant greater.

Unfortunately most of the above deductions apply only to the United States, as it was the only country for which Prof. Coffin made his calculations from the original journals. As to printed meteorological journals, they were very scarce until within a late period, and many of these were not to be had in the United States. Therefore published means and abstracts had to be relied upon, and these gave only the number of observations for each wind. It might be thought that the results of the self-registering anemometers now in use in so many meteorological stations would give abundant material for the answer to this question, but, owing to the recent introduction of these instruments in some cases, and to discontinuity of record in others, comparatively few tabulated records of velocity of winds have been printed.

Yet it seems that the angle between the mean direction calculated, taking into account the number of observations only, and that in which the velocity is considered, seldom exceeds 15°. In case of a very small ratio of resultant it can be much greater, but this small ratio itself shows that the mean direction is not much to be relied upon.

All this leads to the conclusion that it is possible to calculate the mean direction of the wind from the number of observations only without incurring a large error. The map, Plate 13, shows the resultant direction for the number of observations only, as also for velocity, in the United States. I must also explain in what sense I use the words "polar" and "equatorial" winds. Polar designates a wind blowing from a higher latitude towards a lower; and equatorial, a wind blowing from a lower towards a higher latitude. I use these terms in the way which is most generally admitted, to avoid confusion. This agrees also with the manner in which winds are generally designated, so far as we call north wind one that blows from the north towards the south, and not vice versa.

It will be remembered that in the "Winds of the Northern Hemisphere" Prof. Coffin used the words "polar" and "equatorial" in the opposite sense.

Another question, to my mind, more difficult to answer, is as to the value of the observations on the motion of clouds. They may serve two ends: 1, to ascertain the motion of an upper current of the air; 2, to observe the lower current, free from the irregularities often found immediately above the surface of the earth.

Naturally enough, in this case all depends on the height of the clouds observed. Very seldom, if ever, in discussing observations from a journal, can even the approximate height of the clouds observed be ascertained. This alone detracts very much from the value of such observations. Besides this, the cases must be taken into account when there were no clouds, or, the clouds being very high, no

appreciable movement could be observed. All this lessens the value of the observations on motion of clouds.

Generally it is seen, that the clouds move from the same direction as the air near the surface of the earth, which would lead to the conclusion that the lower strata of clouds were those observed.

As to the higher clouds, the *eirri*, as far as known, they move generally from the west, except in the polar regions.

Considering all this, as well as the fact that the motion of clouds is recorded in this work for very few places outside of the United States, I shall not consider the subject in the further deductions, leaving to every one interested to draw his own conclusions from the tables and the map, Plate 1.

The most important works in meteorological science in the last twenty-two years are devoted to the proof of the mutual dependence of atmospheric pressure and winds.

It has for a long time been admitted that in the belts of the trade-winds the air moves from the regions where pressure is high (the polar limits of the trades) towards the low pressure of the equatorial regions. The phenomena here were so simple and regular that the explanation was very easy. In the case of the tropical hurricanes it was also generally admitted that the wind blew towards the low pressure in the centre of the storms. The meteorological phenomena of the temperate and polar regions are much more complicated, and the causes of them less easily detected.

It was Prof. Buys-Ballot who proved the general dependence of the winds on the pressure of the air. In its original enunciation, his celebrated law of the winds declares that the winds will blow from the region where the barometer is above the mean towards that where it is below, and will be deflected 60° to 80° towards the right, owing to the rotation of the earth. He subjected this law to a severe practical test in using it in the system for prediction of storms which had been established at that time in the Netherlands. Buys-Ballot's law of the winds is now very generally accepted, though in a somewhat modified form, viz.: the wind blows from a region of high pressure towards one of low pressure, and is deflected to the right owing to the rotation of the earth. In 1853, Prof. Coffin arrived at a very similar conclusion, saying, "that in the northern hemisphere a wind arriving from its mean direction always finds the point of maximum pressure on its left, and the minimum to its right; while the reverse is true in the southern hemisphere. There seem to be no exceptions to this law." He further states (Proceedings of American Association, 1853, p. 88) that the deflection in this case is 65°; that is, very near to that found by Dr. Buys-Ballot. Even before Professor Coffin, Espy expressed similar views, as seen in his "Philosophy of Storms" and "Meteorological Reports." Very likely the views of the American meteorologists were too much in advance of their time to be generally accepted. When Dr. Buys-Ballot published his law of the winds, meteorology had made much more progress, so as to render such views more easy of acceptance.

This law applies to storms as well as gentle winds, to single hours of observations as well as to monthly and yearly means.

Buchan has rendered a great service to meteorology by extending Buys-Ballot's law to the general phenomena of the winds of the globe. He collected a great deal of information as to the mean pressure of the air, and drew *isobaric lines*, *i. e.*, lines of equal pressure of the air reduced to sea-level, and by considering the prevailing winds he proved that they generally followed Buys-Ballot's law. As this work, "Mean Pressure and Prevailing Winds of the Globe," is very important in the discussion of the winds, I make the following extracts from it:—

"Distribution of Atmospheric Pressure in December, January, and February.

"In these months the highest pressures are grouped over the land of the Northern Hemisphere, and the larger the extent of land, the greater the pressure. The area of high barometer (thirty inches and upwards) embraces nearly all of Asia, all Europe south of the North and Baltic Seas, the North Atlantic between 15°-45° N., the West Indies, North America except the North and Northwest, and the Northern Pacific between 8° and 24° N. There are also two regions of high pressure of comparatively small extent, the one in the South Atlantic, the other in the South Pacific.

"The regions of low pressure are: the northern part of the North Atlantic and North Pacific, including portions of the continent adjoining; the belt of low pressure in the equatorial region, towards which the trade-winds blow, and the remarkable depression in the Antarctic region which is probably subject to little change throughout the year.

"In March the pressure diminishes over Asia, the middle and south of Europe and the United States. Everywhere else except in the tropics it is rising. This rise of pressure is most apparent in the temperate regions of the southern hemisphere. In the north of the Atlantic it is rapidly rising, the average pressure in Iceland now being 29.609 inches, thus showing an increase of 0.34 inch in comparison with January.

"In April, the heavy lines indicating a pressure above the average have all but left Asia, Europe, and the United States, and the isobars of 30 inches bound a belt of high pressure, which completely encircles the globe in the south temperate zone. Pressure continues to rise in the north of the Atlantic, and to the north of North America. And it is probable that a space of high pressure (at least 30 inches) completely encircles the north pole. In this month pressure is more equally distributed than in any other month; for, except the Antarctic Ocean, it scarcely rises anywhere above 30.1 inches nor falls below 29.8. In May, in North Europe, in Greenland, and in the north of North America, pressure attains the maximum of the year. Pressure continues to increase in the south temperate zone, and the isobar of 30.1 now nearly encircles the globe. At this time the highest pressure in the southern hemisphere occurs in the S. E. of Australia, where, at Deniliquin, it is 30.185 inches. Pressure is rapidly falling over Asia and the United States.

"In June, July and August, pressure falls in the central regions of Asia to about 29.5. In this season this diminution of pressure, which may be regarded as entirely

determining the summer climate of Asia, reaches its lowest point. Pressure falls also in the interior of North America, where, at Salt Lake City, it is only 29.7 inches. The annual maximum of the south temperate zone is attained in these months. The isobar of 30.1 goes entirely round the globe, and a still higher pressure prevails over South Africa, and the portions of the ocean immediately to the west and east of it. In these months the arrangement of the isobars may be regarded as being, generally speaking, reversed from that of December, January and February, and in this respect a comparison of these two groups of months is very instructive.

"From this period, pressures increase over the continents of the northern hemisphere, and diminish over the south temperate zone, till the distribution of pressure is regained which has been shown to prevail during the winter months.

"In September and October an interesting feature of these lines is a very rapid diminution of pressure, indicated as taking place in the north of the Atlantic and surrounding regions. This is the season of the year when the first great decrease of temperature takes place, which is accompanied by heavy rains and furious storms. The increase of pressure in Sweden in October, taken in connection with the simultaneous decrease in Greenland, Iceland, the north of Norway, and the British Islands, is interesting as bearing on the transport of masses of the atmosphere from one region into another.

"In November, pressure rises considerably over the continents of the northern hemisphere, and falls in the south temperate zone. And the belt of low pressure in the equatorial regions may be regarded as passing completely around the globe. This belt, towards which the trades on each side of the equator blow, does not occur in the summer months in the Indian Ocean; but, on the contrary, there is a continuous diminution of pressure northward, from Australia and Mauritius to the interior of Asia. It will be seen that in November, as compared with October, the isobars have advanced a little northward from the British Islands to Iceland, and eastward from Baffin's Bay to Iceland, thus indicating a general increase of pressure over the north of the Atlantic and regions adjoining. Coincident with this increase of pressure, there occurs a diminution of pressure to the southeast of it, including Austria, Italy, and countries adjoining the Mediterranean; and in the Atlantic to the south of it, from about latitude 15°-45° N. Probably these extensive oscillations of pressure are part of a general movement of the atmosphere, which, in one of its manifestations, has been generally known to meteorologists as the great November wave, but of which no very satisfactory account has yet been given," (Buchan, p. 577-579.)

Winds within, or near, a space of Low Pressure.—"Of this class, the best example is the low pressure which prevails in the north of the Atlantic and adjoining regions in the winter months. This region of low pressure is bounded to the S. W. by the high pressure of North America, to the S. by the high pressure in the Atlantic, about 30° lat. N., to the S. E. by the high pressure in the interior of Asia. In January, the difference between the average pressure of Iceland and the interior of Asia is fully an inch."

"It is seen from the charts that in Baffin's Bay and east of the Rocky Mountains,

as far south as 40° lat., the winds are N. N. W., N. W., and W. N. W. Crossing the Atlantic, winds in the British Islands, in France, and the north of Germany, from the W. S. W. to S. W.; in Denmark, S. S. W.; near Bergen, in Norway, S.; and at Christiansund and Hammerfest, S. S. E. The relation of these winds to the isobaric lines is the same as that which is illustrated by the winds in storms, in their relation to the isobaric lines of these storms. This has been already stated in a paper by the author, published in the Transactions of the Royal Society of Edinburgh, Vol. XXIV. Part I. p. 201, in the following words: 'The wind in storms neither blows round the centre of least pressure in circles, or as tangents to the concentric isobaric curves, nor does it blow directly towards that centre. It takes a direction intermediate, approaching, however, more nearly to the direction and course of the circular curves than of the radii to the centre.' Or, according to Dr. Buys-Ballot, the angle is not a right angle, but from about 60°

80°. This relation is usually called 'Buys-Ballot's Law of the Winds.'1

"Another well-marked depression is the low summer pressure in the interior of Asia; with reference to which it is seen from the charts that the winds of Eastern Europe and Western Asia are from N. W. to W. N. W. and W.; at Ceylon, S. W.; at Shanghai, S. E.; and on the Sea of Okhotsk, N. E.; whilst in the interior, calms generally prevail."

"The behavior of the winds, as regards the low pressure of North America, is exactly similar to that of the winds in Asia at this season. In all these cases the wind appears to flow round and in upon the space where pressures are low. Even in those instances where the depression over a limited space is comparatively small, such as in Australia during the summer months, the winds observe the same course with respect to it."

"A well-known and remarkable diminution of pressure is that of the Antarctic regions; and though, except in Tasmania and the south of New Zealand, observations are wanting at particular points for a sufficiently long time to give good averages, yet the concurrent testimony of sailors and the inhabitants of these regions all goes to show that, at least on the outskirts of the region, winds are chiefly N. W. or W. N. W.—that is, they appear to flow in upon the space of low pressure. The low pressure in the equatorial regions, towards which the trades blow, is an illustration of the same principle."

"Winds within, or near, a space of High Pressure.—The most prominent illustration of this is the high pressure in the interior of Asia in winter. It is seen from a single glance at the charts that the winds flow out of this space in every direction. The same outflow is seen with respect to the less strongly marked, but still very distinct space of high pressure in North America; owing to the large number of stations available here, this principle is amply illustrated.

"The next most noteworthy area of high pressure occurs in summer between Africa and North America, out of which also the charts show the winds blowing in all directions towards and round upon the surrounding low pressures."

"The following mean pressures, in inches, at 32° and sea-level, occur in Australia in June: At Brisbane, Queensland, 30.062; Sydney, 30.116; Melbourne, 30.178; Adelaide, 30.132; Freemantle, 30.121; and at Deniliquin, in the interior, on a

¹ For Prof. Coffin's determination of this angle, as 65°, see page xxv.

branch of the Murray River, 30.217. Hence a higher pressure occurs at this season (winter) in the interior, and it may be inferred that it is greatest in the southern portion of the interior. The prevailing winds are these: At Brisbane, S. S. W.; Sydney, W. by N. W.; Melbourne, N.; Adelaide, N. E. by N.; Freemantle, N. E. by E.; in other words, the winds blow out from this space of high pressure."

"This behavior of the winds with respect to spaces of high pressure differs in no respect from what occurs on particular days on which the isobaric lines present the same conditions of pressure. Mr. Francis Galton first drew attention to this peculiarity, under the name of Anticyclones, by which name he intended to convey the idea that in cases of high pressure occurring over a limited area, the course of the winds is exactly the reverse of what is seen to prevail in cyclones in which the winds blow round and in upon a space of low pressure."

"The outflow of the air from a region of high pressure, and the inflow upon a region of low pressure, appear to be reducible to a single principle, viz., the principle of gravitation. Given as observed facts the differences of pressure, it might almost be predicted, before calculating the averages, what the prevailing winds are. Indeed, so predominating is the influence of gravitation, that it may be regarded as the sole force immediately concerned in determining the movements of the atmosphere. If there be any other force or forces which set the winds in motion, their influence must be altogether insignificant as compared with gravitation." (Buchan, p. 581 to 583.)

This last passage of Buchan may be more distinctly expressed: in the action of gravity in restoring the equilibrium disturbed by unequal temperature. With a uniform temperature over the whole earth, there would be no wind. In illustration of the dependence of the wind on the difference of pressure, the map of isobars, Plate 14, as well as Plates 2, 4, 5, 6, and others, should be consulted.

Having given the above examples of the manner in which the winds are affected by atmospheric pressure, it is necessary to account for the origin of areas of high pressure, out of which, it is seen, the winds flow.

It must be said that this question is one of the most difficult in meteorology, and far from having received an entire solution.

As the tropical regions present the meteorological phenomena in the simplest form, it is best to begin with them. It has been known for a long time, that above the lower current of the air of the trade winds, flowing in the lower latitudes of the northern hemisphere from N. E. or E. N. E., there exists an upper one from about W. S. W. The existence of this current was proved by the movement of the highest (cirri) clouds always from some westward point, from the strong westerly winds on high mountains in the trade-wind region (the Chimborazo and others in equatorial South America, the peak of Teneriffe, etc.), from the transport eastward of ashes from the eruption of the volcanoes on the island of St. Vincent, (West Indies), and Cosiguina (Central America), and also from the direction of the smoke of very high volcanoes of the tropics. The supposition was then made, that there was a powerful ascending current over the belt of calms and rains near the equator, and that the air thus ascended flowed in the upper regions of the

atmosphere, in a direction contrary to the trade-winds, towards the polar limits of the latter, or to about 30° N. lat. and descended there.

Then the same principle was extended to dry, hot continental areas, where a powerful ascending current must exist on account of the heating by the sun, and this was proved by the great decrease of pressure in summer time.

Buchan extended the idea af ascending and descending currents further, supposing there was an ascending current over every area of low barometer, not only near the equator and on warm continental areas, but also in high latitudes, as on the North Atlantic, the North Pacific, etc. This air, he supposed, descended over areas of high pressure, as for example those existing in winter in Northern Asia and North America. Thus the supposition is, that the air flowing out of areas of high barometers, to a certain extent, comes from above, and again where the barometer is low, air ascends and flows in the higher strata, towards areas of high pressure.

I must repeat here, that this is a supposition, though a very plausible one, and that the actual facts which would prove the existence of such upper currents, with the exception of the so-called counter-tracles in the region of the trade-winds, are very scarce. To these principles I would refer the direction of the wind at Dodabetta in the Neilghiris, in Southern India (above 8000 feet), which is nearly opposite to that observed in the lower strata in Central India, being from the N. W. in summer, that is, from the heated regions of the Punjab, where pressure is very low. In the lower regions, the winds on the contrary are S. E. and S., that is, the air is flowing towards Punjab. Another remarkable fact is the strong, constant, and warm W. wind observed in winter on some mountains near Lake Baikal. At that time of the year, the air is generally calm in lower regions, the cold intense, and pressure high. This west wind of the higher regions would thus seem to be a compensating current, flowing perhaps from Iceland towards the region of highest pressure of Eastern Siberia.

The observations on two of the highest peaks of the Rocky Mountains, above 14,000 feet, have failed to show an upper current of air blowing in a direction different from the lower one. As we have said before, our information as to upper currents is very scanty, and thus great caution seems yet necessary in drawing conclusions.

On the other hand, the influence of pressure on the winds near the surface of the earth is so well authenticated and reliable that we need not hesitate to base further conclusions on it.

The greater part of the earth being covered with water, we can first consider what would be the case if there were no intervening continents. What in this case would be the normal arrangement of pressure on the oceans? A belt of low pressure near the equator, a belt of high pressure at about 30° north and south, and a belt of low pressure about from 60° to 65°, after which the pressure would rise again towards the pole. This gives us three systems of winds at the surface of the earth, easterly (polar) in the lowest latitudes, westerly (equatorial) in the middle latitudes, and again polar in the highest latitudes, in each hemisphere. A

reference to the maps shows that, in the main, such is the actual arrangement of pressures on the oceans and on parts of the continents.

It is easy to see that this is the general conclusion arrived at by Prof. Coffin in his "Winds of the Northern Hemisphere." The main result is thus the same, the study of the winds, alone having shown that this is the case in a great part of the globe, while what we have said as to the pressure of the air shows at least the proximate cause of the prevailing winds. In how far this normal arrangement of winds is disturbed by geographical features, especially by the influence of the continents, will be shown later.

A further condition is the yearly movements of the belts of high and low pressure with the change of seasons. When the sun is in the zenith over the northern hemisphere, the seas under it will be more heated than the southern seas, and the equatorial belt of low pressure, which is also on the seas, the belt of highest temperature, will move northward. Owing to the great specific heat of the water, and consequently to the longer time it takes to cool, this northward movement will continue nearly to the end of the summer. On the other hand, the belt of low pressure in the higher latitudes will also move northward as the temperature rises near the poles, and the storm-tracks can take a more northerly course. The belt of highest pressure between the two of lowest must also take a more northerly position, as the air flows both north and south out from it. There can be no doubt that it holds an intermediate position between the two.

When the sun is in the zenith over the southern hemisphere, the reverse takes place: the equatorial belt of lowest pressure recedes southward, and also that in higher latitudes of the northern hemisphere, as the polar regions are so much cooled that the condensation of vapor there cannot sustain great barometric depressions. These normal or ideal conditions are realized to some extent on the surface of the present oceans, and are the more striking, the larger the bodies of water are. Generally the southern hemisphere has meteorological conditions which approach more nearly to the normal conditions than the northern. Thus, it will be seen by reference to the map of the isobars that the high pressure in about 30° really encircles the globe in the southern hemisphere, while in the northern, the pressure is highest in January at about latitude from 50° to 53° N. in Asia, and in July the pressure is very low, about 30° L. N. on the same continent. Again the low pressure about from 60° to 65° encircles the globe in the southern hemisphere, the difference of pressure under the different meridians not being great, and further south (especially from 70° to 78°) somewhat higher pressure and easterly winds are found. In the northern hemisphere, on the contrary, the lowest pressure is found on two elliptical spaces, in the Northern Atlantic, about Iceland, and in the Northern Pacific, about the Alcutian Islands, that is, where a great extent of water prevails at about 60°, and the ocean is abnormally heated by currents of warm water.

We thus see that at a distance from the influence of water, the above-stated normal conditions are very much interfered with.

If the earth consisted mainly of continents without intervening oceans, very different conditions would prevail. As continents are more rapidly heated than oceans, temperature would be highest very soon after the passage of the sun

through the zenith of a parallel. The greatest heat in our summer would be about the Tropic of Cancer, in our winter about the Tropic of Capricorn, and this would also be the belt of low pressure at that time. The S. E. trade would cross the equator into the northern hemisphere when the sun has a northern declination, and the N. E. trade follow into the southern hemisphere during the other half of the year, giving a variation of the inner limits of the trades of perhaps 40°, instead of the 10° or 12° which are now observed. Further, as dry continents cool also more rapidly, the cold in the polar region of each hemisphere during the winter would be more intense than now, extending to the whole polar region, and coinciding with a very high pressure.

These hypothetical conditions are much more imperfectly realized than those I have sketched before, as the extent of continents is much less than that of oceans. The nearest approach to realization is on the greatest continent, that of Asia, where the highest pressure of winter is a little north of 50° N. If it is not found further north, it is because the continent does not extend much beyond 73° N. In summer, on the contrary, we find the highest temperature in N. W. India between 30° and 35° N., and also the lowest pressure there and in N. China.

The larger the continent the more it approaches to the ideal conditions I have supposed. In Africa, for example, there is a belt of lowest pressure in summer at about 17° N., and the highest temperature is probably still more to the north.

The narrower continents of North and South America are more under the influence of oceans than Africa.

As already seen, the highest mean pressure on the surface of the globe is found in winter on the Asiatic continent. It is necessary to mention here a feature of the climate of this continent, explained by geographical conditions, which has a great influence on the winds, namely, the steadiness of pressure in winter. Pressure is so constant here that, though the barometrical range generally increases with latitude, it is not greater at Jakutsk in N. E. Siberia, under 62° N. L., than in Vienna in Central Europe, Lat. N. 48°, or even in St. Louis in North America, under 39° N. L. The coldest and heaviest stratum of air over Eastern Siberia is prevented from flowing towards the south and east, where pressure is low, by the intervening mountains and plateaus, from 3000 ft. to 5000 ft. high. So long as the cold of winter continues, pressure must, therefore, be high over the cold region of Northern Asia. As it is low in the Pacific Ocean and the equatorial regions, air will flow there from the region of high pressure above the mountains and plateaus. But, as above said, the coldest and heaviest lowest stratum cannot flow towards the Pacific on account of the intervening heights; the quantity of air moving in this direction will not be great enough to supply the deficiency. Thus pressure being lower the whole winter in the S. and E., the winds should be regular from the N. and W., and this is really the case.

On the whole southern and eastern slope of Asia we see a mutual reaction of continental and oceanic influences—the great monsoons. The Europeans were first made acquainted with the regular change of wind and weather in India through the campaigns of Alexander the Great. Not only did the Greeks see this change themselves, but they also learned from the natives with how great a regularity this

change took place; how in all this region the winter was the dry, clear time of the year, and summer the rainy season. The navigators of the sixteenth and seventeenth centuries knew that the monsoons extended much further east than India—to the Indo-Chinese Peninsula, the Sunda Islands, and Southern China.

The cause of the monsoons is this: in our winter the continental regions of Asia are cooler than the surrounding seas, and pressure is higher. The air flows from these towards the equatorial calm-belt in the Indian Ocean, and towards the region of low pressure in the Northern Pacific, as a N. E., N., N. W. or W. wind. As the pressure is continually lower on the seas than on land at this season, this flow of air is very constant. As the air comes from the interior of the continent, and generally also from higher latitudes, i. e., from colder regions, the season when these winds prevail will be a dry season, as the vapor contained in the air will be further and further from its point of condensation the further south and east it flows.

In our summer, pressure is very low over a great part of the Asiatic continent, owing to the heat and ascending current produced by it; therefore the air of all surrounding regions will flow towards Asia, and the movement will be especially rapid in and near Southern and Eastern Asia, as the greatest oceans of the world, the Indian and the Pacific, approach Asia in this direction.

Pressure is higher on the oceans in summer on account of the comparatively cool temperature which prevails there. Thus the movement of air will be reversed, and the wind in summer will blow from the S. W., S., S. E. and E. This summer monsoon will also be very steady, as the difference of pressure is nearly always in one direction during the whole summer—lower on the land.

Not only is the direction of the movement of air different in summer from that prevailing in winter, the influence on the weather is also different. As the air drawn towards Asia has to pass over a great extent of warm equatorial seas, it is laden with vapor, and this vapor will be deposited in copious showers, especially when it meets a mountain chain, which compels it to rise into higher and cooler regions of the atmosphere. Thus the summer monsoon is the time of cloud and rain for all Eastern and Southern Asia, or the wet monsoon. There is no doubt that the condensation of vapor, giving out its latent heat, is a new and powerful cause for the continuance of the movement in the same direction.

The influence exerted by the heated continent of Asia is so powerful that there is no equatorial calm-belt in the Indian Ocean during our summer, but pressure decreases steadily from about 25° S. L., the polar limit of the S. E. trade, till about 30° N. L. in Northern India, the S. E. trade crossing the equator, and being thus converted into a S. and S. W. wind. On the eastern coast of Asia the tendency of air to flow towards the continent similarly acts on the N. E. trade of the Pacific Ocean, which is drawn in as an E., S. E. or S. wind. We see here the normal or oceanic conditions very seriously disturbed by the influence of the great continental mass, Asia.

I must correct here an error which is frequently made, *i. e.*, limiting the monsoons to the tropical part of Asia, *i. e.*, India, Indo-China, and Southern China. Even on the new Pilot Chart published by the British Admiralty in 1872, this

error exists. It can be easily explained thus: in the tropical seas adjoining India and Southern China, the direction of the wind is N. E. in winter and S. W. in summer, and seamen were accustomed to consider as monsoon regions those only where winds of this direction were found. The further north we proceed along the coast of Eastern Asia the more the summer winds become S. E. and E., and the winter winds N. W. and W., yet there is good reason to consider Eastern Asia to the 60° N. L. as belonging to the monsoon region, because here also the winds in winter are from the land; in summer, from the sea, they bring dry, clear weather in the first season, and rain in the second; and last, not least, at both seasons they are very constant. (See Maps, Plates 5, 6.)

For these reasons I consider China, Japan, Mantchooria, the basin of the Amoor River, and the western coast of the sea of Ochotsk, as belonging to the monsoon region.

As to the constancy of the winds I would remark, that the inner regions of India, as, for example, the northwest provinces, Oude, Central India, Punjaub, are generally considered as being situated in the monsoon region, yet the winds are not so constant here as in Japan and the Russian Amoor Provinces.

The continent of Australia may also be considered as belonging to the monsoon region, only the periods are reversed, i. e., our winter is the rainy season there, our summer the dry time. At this season regular S. E. winds are experienced in the northern part of Australia; they may be considered as the S. E. trade, strengthened by the comparatively low temperature and high pressure on the continent. They blow towards the Sunda Sea, and, further on, cross the equator, to appear as the S. W. monsoon on the coast of South China. In our winter, on the contrary, pressure being highest in Asia, and very low in the dry, hot interior of Australia, the N. E. monsoon of China crosses the equator and appears as a N. W. monsoon, bringing clouds and rain to the northern coast of Australia. In these meridians the juxtaposition of the continents of Asia and Australia on the north and south of the line, gives additional strength to the monsoons. Here no equatorial calmbelt is found, neither in our summer nor in our winter, while it exists south of India in the Indian Ocean, as there the monsoons can be said to be single, caused by the Asiatic continent alone, while further east they are double, Asia and Australia both exerting an influence.

It may be asked why the whole Asiatic continent, being equally heated in summer and the air rarefied, does not exhibit monsoons of equal magnitude coming from the Arctic and Atlantic Oceans?

The reason is this: on the Arctic Ocean, pressure is also low in summer, though probably not so low as indicated in Buchan's map of isobars, and besides it is not steady, as on the tropical seas. Yet there is a northern wind coming from the Kara Sea, and blowing through Western Siberia to Central Asia, but it is not as steady as the monsoon of India and China. Besides, as this wind comes from a colder region, it does not bring rain, and thus the secondary influence—condensation of vapor, which is instrumental in producing the monsoons of Eastern and Southern Asia—is not effective here. There flows also a current of air, and a very powerful one, from the Atlantic Ocean towards Central Asia; but, as it

is not from the tropical part of the ocean, it cannot bring much rain and produce the secondary areas of low pressure caused by condensation. Besides, the region of high pressure on the Atlantic is far from the low pressure of Central Asia, and near to that about Iceland; so that the movement in the first direction cannot be very constant. As to the air from over the lower latitudes of the Atlantic Ocean and the Western Mediterranean, it is attracted towards Africa, which is highly heated in summer, and open to the winds from the surrounding seas.

The geographical features of the North American continent explain why pressure and winds are so different over it from what is seen in Asia.

The coldest region of America is known to be to the north of the continent, on the islands and ice-bound seas and sounds north of 70°. Ice and snow being bad conductors of heat, the streams of warmer water are thus effectually prevented from having an influence on the air, and the ice-bound seas to the north of America can cool as well as continents.

But, as the coldest space north of the American continent is not separated by mountains and plateaus from the surrounding regions, there cannot be such a constant high pressure there as on the corresponding coldest space of Asia. It will be remembered that the lowest pressure of the northern hemisphere, especially in winter, exists near Iceland, which is partly due to the warm waters of the Gulf Stream. The coldest regions of America are not separated by any natural barrier from this space, and thus air, even from the lowest, heaviest strata, should flow towards Iceland. That this is the case, is shown by the winds in Greenland and on the most northerly stations of the American continent; they are northerly to a very large extent. Probably the easy intercommunication between the coldest region of North America and the region of low pressure near Iceland, explains why the former has not a high mean pressure in winter. Having not a constantly high pressure, the polar regions of America cannot influence the winds in the temperate and tropical regions of this continent as the coldest region of Siberia, with its constantly high pressure, does influence the temperate and tropical regions of Asia. Next, we find a generally high pressure to the south of the United States, on the Gulf of Mexico, as well as on the western highlands and plateaus of the continent, in lat, from 30° to 40° N. Probably, also, pressure is high to about 60° lat. N. on the eastern slope of the Rocky Mountains, where, the winter being cold, the Rocky Mountains in the west not permitting the air in the lower strata to flow towards the Pacific, and the depression about Iceland being far away, there exist all conditions for a high pressure. But barometrical observations from this region are wanting.

Thus, the Mississippi Valley and seaboard of the United States have in winter regions of high pressure to the S. and W. of them; *i. e.* they are exposed to the influence of winds from different directions, of which those that come from the S. are warm and laden with vapor, and thus able to sustain the precipitations necessary to the progress of storm-centres, while the air from the W. and N. W. is cold and dry.

A country generally level, subjected to such different influences, must have a

very variable climate, and this is known to be the case in the United States. Nowhere in the same latitudes are the variations of temperature and pressure so great and sudden as in the Mississippi Valley and in Texas. On the Atlantic sea-board the variation is somewhat less, owing to the slight protection afforded by the Appalachian Chain.

In summer again, there are no parts of North America which are as strongly heated as the interior parts of Asia, none also where pressure is as low, and thus there are no monsoons comparable in strength and constancy to the summer monsoons of Asia. Especially is this the case with the eastern part of the United States, where the land is so much pervaded by the influence of the sea that there is scarcely a summer depression of the barometer. The Gulf of Mexico is situated just in the latitudes where pressure would be lowest on a great continent, and, owing to the relative coolness of the air over great bodies of water, pressure is nearly as high over the Gulf in summer as in winter. Yet, as there is a rarefaction of the air in the interior and western part of North America, there is a monsoon wind drawn in from the Gulf of Mexico to supply the deficiency. The mean direction of the wind is southerly in summer over a great part of the United States east of the Rocky Mountains. It is more S. E. in Texas, and S. and even S. W. in the States north and northeast of it, partly due to the earth's rotation, and partly also to the influence of the lower pressure in the lake regions on the air over the Gulf of Mexico. On the Atlantic coast the winds have some monsoon features (as was shown by Prof. Coffin in 1848) but still the flow of air is much more from the southwest than would be the case in a real monsoon region, the ocean being to the east.

If, aside from disturbing influences, we consider only the mean direction of the wind, the influence of the Gulf of Mexico is seen to be paramount over a large and important region of the United States, extending from the Mississippi to the Appalachian Chain and from 34° to 42° N. L. The mean direction of the wind is about W. S. W. at all seasons, with a ratio of resultant of about 30. The cause of this is, that pressure is highest at all seasons to the S. and lowest to the N. and N. E.

Having now considered the influence of the pressure of the air on the direction of the winds, the influence on force remains to be shown.

It is easy to conceive, that, the influence of pressure once acknowledged, this influence would be the greater, the nearer areas of high pressure approach areas of low pressure, or, in other words, the nearer any given difference of pressure was found to exist. It was to be supposed, that the more this was the case, the greater would be the velocity of the winds. This has been found to be really the case.

This difference of pressure relative to distance was called by Stevenson barometric gradient. This term of barometric gradient may be applied to the mean direction of the wind, and the rate of progress, as well as to any given single observation. The more the isobars are crowded together, the steeper is the gradient, and the greater will be the velocity of the wind, all other conditions being the same.

There are conditions well known to science in a general way, although not

measured with accuracy, which prevent all winds from reaching the same velocity even if the relative distance of the isobars be the same.

These conditions must be considered in brief.

In the lowest stratum the velocity is lessened on account of friction on the surface of the earth, while the higher are also more or less affected by the friction of the different strata on each other.

The winds on the ocean will be less affected in this way, because of the smooth surface of the water. The greater velocity of the wind on the sea is well known. The figures published in the "Quarterly Weather Reports" of the Meteorological Office, of London, very clearly show the decrease of velocity in the interior of Great Britain even in level parts of the country.

The following table shows this for the United States. I give the mean velocity of the wind in a group of inland stations (Eastern New York) compared with that of the sea-coast (Cape Cod and adjacent islands) and also with the summit of Mount Washington, the highest peak of the New England States.

	Summer.							Winter.								
	N.	Zi Ei	ы	E S	κά	S. W.	W.	N. W.	Ä.	N. E.	ы́	S. E.	νi	S. W.	W.	N. W.

Cape Cod and islands .	7.8	10.9	5.3	9.0	6.7	9.6	9.3	6.3	19.9	20.5	12.2	16.1	10.6	10.9	10.9	20.0

MEAN VELOCITY OF THE WIND. MILES PER HOUR.

Mount Washington having the freest position, the strength of the winds there must be considered as more nearly normal than at the other places. The N. W. winds are the strongest, both summer and winter. But in the vicinity of Cape Cod, the N. E. winds coming over the smoother surface of the sea, are the strongest.

It is safe to present the following rules for the velocity of the wind. It is greater:

- 1. On high isolated peaks, than at low stations.
- 2. On the seashore, and especially on isolated islands, than in the interior of continents.
 - 3. In level countries than in countries surrounded by mountains.
 - 4. In prairies, and especially desert countries, than in wooded regions.

These rules apply to the local positions only. But we may remark that it is possible to mention some regions where the velocity of the winds is greater, others where it is less, than the average over the whole earth.

To the latter belong the equatorial calm-belt, and the calm-belts at the polar limits of the trade-winds. It would be wrong to imagine that any point on the

One summer and two winters, 1870-71, and January, February, and December, 1872.
5 July, 1875.

surface of the earth has perpetual calms. The calm-belts themselves are not constant, but move in the different seasons, and besides, the calms are more or less frequently disturbed.

In the trade-winds belts also, notwithstanding calms are very rare, the velocity of the wind is probably less than the average of the globe.

Probably the part of the earth where the winds have the greatest velocity, is found between 40° and 60° Lat. S., where very strong westerly winds are prevailing the whole year. The cause of this is the great difference in the pressure of the air at a small distance, or in other words the steep barometric gradient.

The great difference of the mean velocity of the winds blowing over a region, and of the progress of the air in a certain direction, should be borne in mind. Where the winds are weak, but always from one direction, as in the trade-wind region, the total rate of progress measured in miles will be considerable, frequently greater than in regions where strong winds blow from different directions. It is even possible that the winds may be so counterbalanced by one another, that there will be no resultant direction, so that the definite result, as far as progress of the air is concerned, would be the same as if absolute calms had prevailed all the time.

So far as regions are considered, where the mean direction of the wind does not vary, or varies but slightly in the different seasons, the mean annual direction with rate of resultant, gives a tolerably fair idea of the character of winds in such regions.

It is quite different where regions with very great variations in the yearly direction of the wind are considered. Here the annual direction will give but a very imperfect idea of the character of the winds. This is the reason why, as far as possible, I have always placed at least two contrasting seasons, summer and winter, in giving the percentages of the winds and the mean directions in the small tables which follow, and serve to illustrate the winds of different regions of the world. This is also the reason for constructing the two maps, Pl. 5 and 6. The same attention has been given to this subject by Prof. Coffin in his extensive tables arranged in Zones, in Series B of this work, the number of observations being given generally for the four seasons, sometimes even for each month. How far the consideration of the annual result alone would mislead, the following table will show:—

	Year.		Summer.	•	Winter.		
	Mean direction,	Rate of resultant.	Mean direction.	Rate of resultant.	Mean direction.	Rate of resultant.	
57°-58° N. L.—Eastern Scotland Greenwich, England 50°-55° L. N., 0° to 65° long. W.— Atlantic Ocean N. W. Ohio Middle Tennessee Hakodade, N. Japan	S. 60° W. S. 62° W. S. 53° W. S. 65° W. S. 64° W. S. 79° W.	28 17 23 35 21 22	S. 65° W. S. 61° W. S. 46° W. S. 59° W. S. 51° W. S. 12° E.	$ \begin{array}{r} 18\frac{1}{2} \\ 28 \end{array} $ $ \begin{array}{r} 23 \\ 39 \\ 22 \\ 42 \end{array} $	S. 62° W. S. 55° W. S. 65° W. S. 73° W. S. 65° W. N. 59° W.	40 25 36 37 28 63	
Pekin, N. China	S. 64° W. S. 30° W. S. 61° W.	11 18 29	S. 16° E. S. 54° W. S. 58° W.	18 85 88	N. 54° W. N. 47° E. N. 37° E.	30 68 59	

It is seen from the foregoing that in Western Europe, on the Atlantic Ocean and in a certain region of the United States, the mean direction of the wind in the year, summer and winter, is between S. W. and W. S. W., and the difference between the two seasons very small. If the rate of annual resultant is not greater, it is because at all seasons there are many winds coming from other directions than the prevailing one.

In Pekin and Hakodade the mean annual direction is nearly the same as at the above named places, but the ratio of resultant is small for another reason: the winds of summer and winter being nearly opposite to one another, the resulting annual movement is small. Yet at each of the seasons the winds are very steady. The angle between the mean direction of the wind in winter and summer is 142° at Pekin, and 133° at Hakodade, or more than $\frac{3}{8}$ of a circle, and only from 3° to 20° at the above cited places of Europe and America. Again, the mean annual direction of the wind and ratio of resultant, in Southern India and Ceylon, are very similar to those observed in Europe, but the mean direction of winter and summer nearly opposite to one another, with an extremely great ratio at both seasons, there are conditions as dissimilar as possible to those of Western Europe.

In the pages which follow, the results to be drawn from the observations on the winds are considered by geographical divisions.

SPECIAL DEDUCTIONS.

GREENLAND AND ARCTIC AMERICA.

The information we have on the winds, as well as on the general climate of Arctic America and the adjacent islands, is more extensive than that on any other Arctic region, Northern Norway excepted. Our knowledge of these regions is mostly due to Arctic explorations. The Arctic Archipelago, north of the American Continent and west of Greenland, was explored almost continuously by British expeditions for more than thirty-five years (1818–1855), in search of a northwestern passage.

The results of these expeditions are of high value to science, especially as the inducements to explorations in this direction can scarcely ever return. The bays and straits between the islands are probably the most ice-bound in the world.

Smith's Sound and Northern Greenland have been explored by the American expeditions of Kane, Hayes, and Hall.

According to the most authentic Arctic authorities, Smith's Sound offers the best route to the Pole, the sea between Spitzbergen and Nova Zembla perhaps alone excepted. It is entirely frozen only a short time, and does not present serious obstacles to navigation in steamers. This gives us reason to expect further knowledge of those regions which were so successfully penetrated by American explorers, with very inadequate means at their disposal.

A German expedition wintered in Eastern Greenland, 75° N. Lat.

We know much less of Western Arctic America; few expeditions having wintered there west of 100°. Our knowledge of the interior of British America is also less than of the Arctic Archipelago, though it is much more easy of access. More information relative to this region is very desirable.

Our knowledge of the climate of Arctic regions generally having been mainly derived from observations made in the Arctic Archipelago of America and in Smith's Sound, it is necessary therefore to inquire into the geographical position of these regions. They are situated from nearly due north to W. N. W. of Iceland, where, as was stated above, exists the lowest pressure of the northern hemisphere, nearly the whole year round, but especially in winter. This must lead to the prevalence of northerly and westerly winds. Accordingly in the stations in Smith's Sound northeasterly winds were found dominant, owing to the influence of the strait, and also to the position, N. N. W. of Iceland. (See Map, Pl. 2.)

There are great discrepancies in the results obtained at the different stations,

but these are easily accounted for, if we remember that the period of observation was short, mostly one year only, and that the climate of the Arctic regions is very changeable; still there are some differences in the direction of the winds which can only be ascribed to their geographical position. Thus Northern Greenland has the greatest prevalence of the true polar winds, northeast, and this is due in no small degree to its proximity to Iceland, as well as to the open water of Smith's Sound near a very cold continental area.

The most northerly stations west of Smith's Sound, as Northumberland Sound and Port Refuge, have the least amount of northern winds. This is, no doubt, owing to their distance from Iceland, and, probably also, to a partly open sea to the northward of them. If there is really an open sea in this direction, the pressure there must be lower in winter than on the ice-bound straits of the Archipelago. This would give rise to southerly winds to equalize the pressure, and thus explain the greater number of these winds in Northumberland Sound and Port Refuge. They do not prevail at these places, because the depression about Iceland is still felt there as well as the depression which must exist on the open waters of Davis' Strait and Smith's Sound. As the other stations of the Archipelago, except Melville and Dealy Island, are much nearer to Davis' Strait, they must feel its influence much more, while a great extent of islands and frozen bays and sounds separate them from the northern partly open Polar Sea.

The prevailing northerly winds in summer can be explained partly by the same cause as those of winter—the low pressure about Iceland. It is true the barometer near Iceland is not as low in summer as in winter. But in the Arctic zone of America the pressure rises also, especially from February to May; in the last-named month it is the highest of the year in most of the stations of this region.

It is probable that the pressure continues to rise in the circum-polar zone till July, thus causing the northerly winds of Arctic America. At this season air is also drawn towards the interior of North America, especially towards the region between the Rocky Mountains and 95° W. Long.

Arctic America is noted for its frequent calms in the colder part of the year—a feature observed by nearly all who wintered in these regions. They are, however, recorded in a very discordant manner in the journals of observations, showing there was a great difference in the meaning of the word "calm." This want of agreement has prevented a more elaborate discussion of this phenomenon, one of the most important in regard to the movements of the atmosphere.

Dr. Bessels has calculated the percentage of what he calls "absolute calms," for the hours when a self-registering wind-vane did not indicate any movement of air whatever, for the second winter-harbor of the U. S. Expedition, under Capt. Hall, at Polaris House or Lifeboat Cove.

			Hours of Absolute Calm in 1000.			
November,	1872,	74	January, 1873, 298	March,	1873,	188
December,	44	47	February, " 79	April,	4.6	179
Ť				May,	1.0	116

Average for seven months, 140.

I should remark, that in many of the stations the proportion of calms increases

towards March and April. In these months the cold is still intense in this region, and the pressure generally higher, so that barometric poles or areas of highest pressure are frequently met with. They are generally accompanied with calms or light winds. On the other hand, the indraught towards Iceland is less, as pressure has also risen there. (See Tables, Zones 2, 3, 4, and 5.)

In cold continental areas of lower latitudes, especially in Siberia, the greatest number of calms will be experienced in mid-winter, the time of lowest temperature and highest pressure. In March and April, when temperature is much higher, pressure decreases, and so also the number of calms.

The following figures give the percentage of winds in Greenland. Winter and summer are chosen as the two contrasting seasons of the year.¹

All these stations except Sabine Island are situated on the western shore of the greatest island of the world, an island covered with large sheets of ice, and the temperature of which is much below that of the surrounding seas in winter, spring, and autumn; Smith's Sound is open the greater part of the year, though bearing large floating icebergs. Monsoon winds must be expected in these conditions, and this is really the case.

The winds of Polaris Bay⁴ have a peculiar interest, this being the most northerly station at which civilized man has ever wintered.¹ Polar winds prevail largely in spring and winter. Yet there is a great difference between the N. E. and E. winds. The second prevail if the number alone is regarded, but the N. E. prevail

¹ In all cases, except when specified, the percentages are calculated from the winds collected by Prof. Coffin.

² From the observations of Dr. Bessels, of Capt. Hall's Expedition.

³ Observations of the Second German Polar Expedition, under Capt. Koldewey.

⁴ I owe this information on the winds of Polaris Bay and Lifeboat Cove to Dr. Bessels, who has kindly permitted the use of his observations.

largely if we take into account the number of miles. And this may be done safely, as the expedition of Capt. Hall had an anemograph of Robinson's plan. The east winds then seem to be a weak local land-wind, caused by the difference of temperature of land and sea. The N. E. winds, on the contrary, are the true polar currents, flowing towards the barometric depression about Iceland.

In summer the S. W. wind prevails as to time, but the excess is on the side of the N. E., if the number of miles is considered, but of much less amount than in winter and spring.

In the second winter station of Capt. Hall's party, Lifeboat Cove or Polaris House, as also in Hayes's Station, Port Foulke, in the vicinity, the N. E. prevail even more than in Polaris Bay in winter and spring. The W. and N. W. are entirely wanting.

In the tables of Professor Coffin, the winds at Rensselaer Harbor, Kane's winter station, were recorded with reference to the magnetic direction. As the magnetic declination is known to be 108° 12′ W., I give below the true mean direction of the wind in this locality, and also that recently calculated by Dr. Bessels for Polaris Bay. In the Map, Pl. 2, the true direction is given.

			Rensselaer l	Harbor.	Polaris Ba	y.
						Rate of Progress.
			By Hours.	By Miles,	Mean direction.	Miles.
Spring			S. 75° E.	S. 87° E.	N. 38° E.	6279
Summer			S. 1° W.	S. 36° E.	S. 2° W.	1828
Autumn			N. 78° E.	S. 86° E.	N. 26° E.	2685
Winter			N. 65° E.	N. 63° E.	N. 21° E.	4394
\mathbf{Y} ear			S. 86° E.	S. 89° E.	N. 40° E.	11,392

The observations of Rensselaer Bay are thus shown to agree, to a considerable extent, with those of the surrounding stations. The winds are more easterly than at Polaris Bay at all seasons, and do not vary as much as at that station, the difference between winter and summer being only 91° instead of 161°. See Map, Pl. 2.

The Danish settlements of Northern and Southern Greenland (all on the west coast of the island), Upernavik, Jacobshavn, and Godthaab, have largely prevailing east winds (from the land) in winter, and west winds (from the sea) in summer. As the force of the winds has not been accurately ascertained, we cannot say whether the N. E. are much stronger than the East, as in Polaris Bay. In the summer the rocky surface of the interior (as Greenland is not all covered with ice) is highly heated by the sun, it draws in the air from the colder sea, which is cooled by the large number of icebergs floating southward.

We know much less about Eastern Greenland, the country being entirely uninhabited. Yet the 2d German polar expedition having passed a year near Sabine Island, 75° L. N., near the coast, we are able to say that the prevailing winds are N., especially in spring, autumn, and winter, while S. winds are nearly as frequent as N. in summer. The N. prevail here to a less degree than the N. E. at Lifeboat Cove and Port Foulke; but it would be rash to decide from so short a period and so few observations that the polar winds are really less prevailing in the east than in the west of Northern Greenland. The eastern coast of the island

being nearer to Iceland, where pressure is low, we might infer that the contrary should be the case, if all local influences were eliminated. Nearly all the storms near Sabine Island come from the N., and the mean force of this wind is very much greater than that of any other wind.

The constancy of the polar current in Northern Greenland is indirectly proved by the small precipitation of rain and snow. The quantity of snow falling at Polaris Bay and Lifeboat Cove was scarcely measurable, according to Dr. Bessels. He thinks the glaciers of Northern Greenland are the remnant of a former age, when the climate was different. The snow and ice that melt in every summer are not now replaced by new snow, so that the glaciers must be decreasing.

The German expedition did not encounter a heavy snow-fall, and the parties who, in sledges, explored the interior, were quite astonished at the constant brilliancy of the sunshine of the Greenland summer.

In Arctic countries the sea is warmer than the land in the mean of the year; during a very short time only, in summer, are the conditions reversed. The pressure is generally higher on land, so that we must expect to see a prevalence of landwinds in the mean of the year. In looking at the map of the polar regions (Plate 2) an easterly mean direction is seen to prevail in all stations in Greenland, that have the open sea to the westward; and a westerly in the stations of the Arctic Archipelago, which have the sea to the eastward.

By sea, is meant here the more or less open waters of Baffin's Bay and Davis Strait, and not the more ice-bound straits and inlets of the archipelago. Ikogmut and St. Michael in northern Alaska have easterly winds, directed towards Behring Strait. In Ustyansk, in the extreme north of eastern Siberia, the mean yearly direction is nearly due south—as we might infer from the fact that the Arctic Ocean lies to the north of this place. Hammerfest, Vardo, and Bossekop, in extreme northern Norway, have also prevailing southerly winds for a similar reason.

The extreme prevalence of land-bound (Mediterranean) seas, north of the North American continent, greatly affect the character of the region considered in a climatic point of view. As land-bound seas in these latitudes will be also ice-bound, the air over them would cool as over a continent, so that places situated on the shores of such seas will have a cold continental climate in winter, spring, and autumn. This cold will not, however, be followed by a comparatively warm summer, as is the case on polar continents far from the influence of the sea. The melting ice over the sea absorbs the heat of the sun's rays. Thus we have a continental climate during three-quarters of the year, and an oceanic during the remaining summer quarter. This is the case in the Arctic Archipelago. It has one of the coldest climates of the world, the winter being even colder than in northern Greenland, and only a little warmer than in Iakutsk in eastern Siberia, and the summer also extremely cold.

The percentage of winds is as follows:—

¹ See "Die Zweite Deutsche Nordpolarfahrt," Leipzig, 1874.

	Summer. Winter.
Zone 3, No. 3. Port Refuge	$\begin{array}{c ccccccccccccccccccccccccccccccccccc$

The prevalence of the N. and N. W. winds is here strongly marked, especially in winter. At two of the stations more than half of all the winds come from the N.W. The exception presented by Port Bowen, where E. winds largely prevail in winter, is explained by the large land-mass to the E. The winds of the inland and western stations of Arctic America, as well as the Arctic Ocean in their vicinity, show more irregularities.

From the foregoing table it appears that in Northern British America (Forts Norman, Simpson, Enterprise, Reliance, Franklin, and Anderson) there is no accordance in the direction of the winds. They seem to vary much according to locality. This is a very cold region, and being continental, calms are much more prevalent in winter than in the Archipelago. We must expect to find here higher pressure in winter than further to the east, because the depression about Iceland is not so near.

The great distance of the Atlantic depression and the mountains which lie between this region and the Pacific depression, also explain the undecided character of the winds in winter.

We have fewer observations in the summer. Among these, Fort Franklin has prevailing E. winds, coming from Great Bear Lake, where the ice does not melt till the end of the summer.

In Alaska monsoon winds are seen to prevail from the N. E. (the land) in winter, 86 July, 1875.

S. W. in summer. In Behring Strait southerly winds are also more numerous in summer, while the Arctic Ocean northward of it has northerly winds at the same season.

In the last two stations lying near Hudson's Bay, a monsoon influence is exhibited in the S. winds of winter. Hudson's Bay does not freeze entirely, and thus the wind will blow towards it from the land. (See Maps, Plates 5, 6, and 14.)

TEMPERATE ZONE OF AMERICA WEST OF THE ROCKY MOUNTAINS.

On the coast of Alaska and further south in Washington Territory, the winds have a monsoon character. The cause of this is the difference of temperature and consequently of pressure on land and sea, producing a current of air from the land in winter, and from the sea in summer.

It is necessary to remember that the warm current of the Kuro-Sivo, the Gulf Stream of the Pacific, passes, in its return to the south, near to this coast, and there must be a diminished pressure over the region, at least in the colder part of the year. The interior of the continent is very cold at that time, and therefore the pressure of the air must be high there.

In the summer theré is a narrow cold current passing between the coast and the Kuro-Sivo, while at the same time the interior of the continent has a great excess of temperature over the coast, and, as in other dry and warm continental areas, the pressure must be low.

There is no country of the world where the temperature of the summer increases so much as we go from the coast to the interior as on the Pacific slope of America, from Alaska to Lower California. The summer isotherm of 59° passes near San Francisco on the coast of California, and is supposed to reach the polar circle on the Yukon River, in the interior of Alaska, a difference of 28° in latitude. Fort Miller, in the interior of California, has a summer temperature of 85°.5, and Monterey, on the coast, and in the same latitude, but 59.0; difference 26.5 F. The percentage of winds in Alaska and Washington is given below, and, with the help of the maps, Pl. 5 and 6, will serve to illustrate the winds of this region. Plate 14 gives the atmospheric pressure.

¹ From Report of Chief Signal Officer, 1874.

If, as was said before, the winds of this coast have monsoon features, these monsoon winds do not overpower others, especially in winter. At that season of the year the pressure is high in the latitude from 25° to 35° N. on the coast of California, and in the same latitudes on the Pacific Ocean. Winds from this region are quite frequent, and passing over the warm waters of the Japanese current, give a very warm climate to the whole coast. The winter temperature of Sitka is equal to that of New York, and above that of St. Louis.

It seems to me that the S. E. winds which are so frequent on this coast, are, partly at least, the deflected S. W. winds of the Pacific. The mountain-chains give them a direction from the S. S. E.

The Aleutian islands are very near to the centre of lowest pressure on the Pacific, at least in winter. They occupy a position similar to that of Iceland in the Atlantic; the same may be said of the island of St. Paul in Behring Sea. The storms are frequent and severe, and the winds polar and equatorial in turn, without a marked predominance of either. In summer the centre of depression moves to the northward and inland, and accordingly the winds are principally from the south.

In Washington Territory the winds of the coast-region are very similar to those of Sitka. In the interior of Washington and Oregon the winds have no strongly marked monsoon character. (See also Maps, Pl. 5, 6, 8, and 11.)

	Sum	ner.	Winter.	
Percentages S. E. Washington N. E. Washington N. B. Oregon	3 7 3 20 3 7 3 20 3 8 5 3		4 8 2 23 13	B B B B 36 3 11 36 3 11 33 15 11

The S. W. is here the prevailing wind, winter and summer, as in the same latitudes on the oceans and in Europe. We must see in these winds a continuation of the equatorial current of the Pacific, which crosses the coast-ranges and descends into the valleys, while part of it is deflected by these mountains and appears as a S. E. wind at Sitka. The winds of California differ in some respects from those of the northern Pacific coast. They are westerly at all seasons of the year, more S. W. in winter and N. W. in summer. The winds of the summer are very strong and steady, giving to the California coast a peculiar climate—a summer colder than anywhere in the same latitude even in the southern hemisphere. In some places the prevailing winds in summer are S. W., and the mean direction also south of W. This is probably due to the position of the coast, so that the S. W. seems to be a local sea-wind. At San Diego the number of miles was also observed, and I have calculated separately the percentages for the number of observations and for the number of miles, in the three summer months.

	San Diego	_			Sur	nmer.			
		N.	N. E.	E.	S. E	S.	s w.	w.	N. W.
No. of Observations No. of Miles		 1	10 2	11 0.6	13 8	7 12	29 12	19	7 5 5

Thus the N. W. wind largely prevails if the number of miles is taken into account. The following is the percentage of winds in California, Oregon, and Nevada.

				Sumi	mer.							Wii	iter.

Thus in summer, westerly winds very largely prevail in this region, while in winter the ratio of resultant is much smaller in California and Oregon, and easterly winds prevail further north, as shown also by the map, Plate 8.

The geographical features of the North American continent are such as to exclude a great part of it from the influence of the Pacific Ocean. The mountainchains are higher in the west than in the east, and, what is more important still, there is a very extensive plateau occupying nearly all the western half of the continent, between 34° and 42° N. L. The eastern part of this plateau, in eastern Wyoming, Colorado, and New Mexico, and in northwestern Texas slopes gradually towards the east—the valley of the Mississippi—and is thus subjected to the influence of the Gulf of Mexico. This influence is especially felt in summer,

when the heated and rarefied air of the plains draws in that of the surrounding regions.

On the west these plateaus are walled in by ranges of mountains, and the indraught of air from the Pacific slope is thus prevented.

We know that there is a depression of the barometer in summer over the plateaus of the interior, but there are yet too few observations to decide as to the region where this depression is greatest. It is, however, most probable that it is in Utah.

There is also a low region, where pressure must be low in summer, that is the valley of the Gila and lower Colorado. The heat is extreme there, Fort Yuma and vicinity having the warmest summer in America, and the ascending current must be very powerful. Air is drawn in towards this hot region, and, owing to its geographical position, principally from the south, from the Gulf of California. (See also Map of Isobars, Pl. 14, and of Winds, Pl. 8 and 11.)

The following table gives the percentage of winds of the region east of the coast:—

				Sun	nmer.							Wir	iter.

The predominance of southerly winds in summer, as shown by this table, is very great, and it must be remembered that the greatest part of this region is mountainous, and thence great local discrepancies should be expected. The period of observation was short in nearly all cases. Considering this, the agreement between the different regions is very satisfactory. (See Plates 8 and 11.) In Utah there are less southerly winds in summer, and still less in Montana. But this is easily explained. As Montana lies north of 44° N. latitude where there is no extensive plateau, and the mean height of the Rocky Mountains is less than to the south—the westerly winds from the Pacific can therefore readily reach Montana.

We should also expect to see southwesterly winds in winter in Montana, as in California and Oregon. This is really the case. In Arizona and New Mexico, on the contrary, the winds are much more northerly in winter than in summer. I give below the mean direction of the wind in some of the regions here considered. (See also maps, Plates 5, 6, 8, and 11).

TEMPERATE ZONE OF NORTH AMERICA, EAST OF THE ROCKY MOUNTAINS.

This region has much in common with Arizona and New Mexico, as to the mean direction and percentage of its winds. In summer a strong current from the south sets in to supply the air which is rising on the interior plateaus. In the winter, on the contrary, the prevailing winds are N. W. and the mean direction generally between N. and W. In winter the winds are more variable than in summer, and even southerly winds are sometimes experienced. The boundaries of this region are the great axis of the continent on the W., the Rio Grande on the S. W., the Gulf of Mexico on the S. E., and the Mississippi on the E. The northern boundary is rather doubtful, but yet, as far as 45° N., winds from the S. E., S., and S. W. prevail in summer. (See also maps, Plates 5, 6, 8 and 11.)

In Texas the winds have nearly the same direction as in Arizona and New Mexico, but the percentage of southerly winds in summer and northerly in winter is much greater. The winds in Texas have very strong monsoon features. This is due in a great measure to the proximity of the Gulf of Mexico. The state, except its extreme western part, is wholly open to the winds from the Gulf, and they must be strongly drawn in towards the land in summer, as the continent is much warmer than the sea. We have seen that there is a monsoon drawn in from the small and narrow Gulf of California to supply the deficiency in the interior. We must expect a much more powerful monsoon from the Gulf of Mexico. Winds in Texas, other than S. and S. E., are all but excluded from April to September.

In winter the winds are more northerly, but not N. E. or E. N. E. as in the trade-wind regions of the same latitudes, but N. and N. W., i. e. winds blow from the Staked Plain and other continental areas towards the Gulf of Mexico. Yet the prevalence of these winds, if we take the number of observations only, is not so great as that of the S. E. in summer. But the N. winds are extremely violent in Texas; they are the famous northers so well known and dreaded by seamen navigating the Gulf of Mexico, and also by travellers in Texas, especially because of the suddenness of their appearance. They are especially frequent in Central Southern Texas, about San Antonio, while the north winds east of the Guadalupe River are not so sudden and violent, resembling in fact rather the northwesters of the eastern States.

The cause of the violence of these winds must be sought to the southward in eastern Mexico. This country has not as regular a climate, with small barometrical variations, as other tropical regions of the same latitude. From December to March there are frequent storm-centres, with low barometer, passing there, as also on the eastern coast of Central America. A barometrical depression in Mexico or southward of it must draw in the air from the interior of Texas and New Mexico, where the pressure is high in the winter months. In April and May, when the barometrical variations are less in Mexico, the northers are less frequent, and cease altogether from June to September during the tropical rainy season, when barometrical variation is at minimum in Mexico. To illustrate this I give the mean and extremes of the pressure of the air at Vera Cruz. (See also Plate 14.)

¹ From the observations by Dr. Berendt, manuscript collection of the Smithsonian Institution.

In the extreme south of Texas, at the mouth and in the valley of the Rio Grande, the S. E. winds are much more frequent, even in winter, than in the rest of the State. This is an intermediate region, partaking of some of the features of the Mexican climate, where easterly winds prevail the whole year. Yet the lower Rio Grande region is subject to violent northers. This seems to lead to the conclusion that in the other regions of Texas, where northerly winds prevail in winter, they are not all northers, there being also north winds of moderate force blowing towards the Gulf.

The mean direction of the winds in the different portions of Texas, is as follows:—

	Spring.	[Summer.	Autumn.	Winter.
	Mean direction.	Ratio of resultant.	Mean direction.	Mean direction. Ratio of resultant.	Mean direction. Ratio of resultant.
Western Texas, N. of 30° N. N. Texas, E. of 98° W. Texas, lat. 31°-32° N., long. 94°-97° W. S. Central Texas, lat. 29°-30° S. E. Texas Rio Grande Valley Forts Brown, Polk andMatamoras	S. 3 E. S. 23 W. S. 30 E. S. 56 E. S. 73 E. S. 60 E.	. 29½ . 24½ . 27 . 21½ . 32 . 37 . 56 . 52	S. 7° E. 15 S. 12 E. 52 S. 14 E. 54 S. 32 E. 46 S. 33 R. 53 S. 46 E. 46 S. 43 E. 82 S. 44 E. 70		N. 57° W. 33 N. 70 W. 13 S. 72 W. 08 N. 14 W. 20 N. 39 E. 23 N. 24 E. 32 N. 62 E. 19 N. 84 E. 16½

The summer, as is shown by these tables, and the maps Plates 8 and 11, is the season in which the wind is most constant, the mean direction at all stations being between S. 7° E., and S. 46° E., and the ratio of the resultant very great, except in Western Texas. In the three last regions, nearest to the Gulf, the direction is more S. E., while in the more northern part of the State it is rather S. or S. S. E. The influence of the earth's rotation is here clearly seen. The wind begins as S. E., but soon is deflected to the south, and in its further course passes to the W. of S.

The agreement is not as exact in winter, probably because we have only the number of observations, and not the force of the wind. As the N. and N. W. winds are known to be the strongest, the mean direction would be much nearer each other in the different parts of the State, if we knew the force of the winds. Yet in all cases it would be seen to be more easterly on the lower Rio Grande near the Mexican frontier.

Spring and autumn are transition seasons, and in a country with monsoon winds, as Texas, there is very little to say about them. Generally spring is more analogous to summer, and autumn to winter. (See Plate 8.)

I must further remark as to the S. E. winds of the summer, that it would be an error to consider them merely as sea-winds blowing only during the day. They are stronger in the afternoon, while about sunset there is generally a calm. But about 9 P. M. the S. E. springs up again and blows till morning, when there is a second calm. I had occasion to observe this, in the summer of 1873, in the country between the Nueces and Guadalupe, and old residents of San Antonio informed me this was the regular course. (See the figures showing the number of observations and the force of the wind at 7 A. M., 2 P. M., and 9 P. M., at the last

place for the year 1872. (Zone 13, No. 13.) Even at stations on the Gulf coast, there are scarcely any land winds (N., N. W. and W.) observed in summer, which would be the case if there was a regular alternation of land and sea breezes.

North of Texas, throughout the whole region between 34° and 44° N. and the Rocky Mountains and Mississippi, the winds have also monsoon features, but more subdued. The prevailing winds of this region are N. and N. W. in winter and S. in summer. The cause is the same as in Arizona, New Mexico, and Texas. There are some irregularities in the mountain region (Central Colorado) but east of the mountains, in Nebraska and Iowa, the general character is again strongly marked. It is less the case in S. E. Minnesota, but even there the winds are southerly in summer, and deflected to the S. E. by the direction of the Mississippi Valley. In N. E. Arkansas and in Missouri the difference between winter and summer is still less marked. This is an approach to the character of the region between the Mississippi and the Appalachian chain, where there is no difference whatever between the seasons, the mean direction being about W. S. W. the whole year round. (See Plate 8.)

The tables for this work were printed before the results of observations on two high peaks of the Rocky Mountains could be obtained, both over 14,000 feet high. A meteorological station was established on Pike's Peak in the end of 1873, by the United States Signal Service, and the "Report for 1874" contains the means of observations for the first twelve months. I have given them in percentages, adding the station of Colorado Springs, at the eastern base of Pike's Peak. On Mount Lincoln the observations were made under Professor Hayden's geological survey of the territories, from 21st July, 1871, to the end of January, 1874. Both Pike's Peak and Mount Lincoln are situated in the central part of Colorado.

								Sum	mer.							Wir	iter.

The difference between Pike's Peak and Colorado Springs seems to give a much greater proportion of S. W. and W. winds at the higher station, and a smaller amount of N., especially in summer. This agrees with the generally entertained opinion as to the prevailing direction of the upper atmospheric current from the W. S. W. in the middle and northern latitudes. In any case more observations are necessary in this respect.

The mean direction of the wind in the region north of Texas is:-

87 July, 1875,

Here, again, as also shown by the maps (Plates 8 and 11), summer is the season which exhibits more regularity, the mean direction being everywhere between S. E. and S. W. The ratio of the resultant is greatest in the Indian Territory and Kansas, *i. e.*, due north of the Gulf coast of Texas, and far from the influence of mountains. It is least in Missouri and N. E. Arkansas.

In winter the winds incline much more to the west than in Texas, being even S. of west, in East Missouri, N. E. Arkansas, and in S. E. Minnesota, i. e., in the extreme east of this region. Except in these regions there is a tolerably good agreement between the other stations.

The greatest difference between this region and Texas is seen in spring, as shown in Plate 8, when the winds are everywhere more or less westerly, except in the Indian Territory. Probably the cause is this: Texas being situated in a lower latitude is earlier heated, and the air from the Gulf of Mexico is sooner drawn in. The region here considered being further to the north, ascending currents are not established as early. Besides, when the lowlands between 34° to 42° N, are already heated, and an ascending current established over them, the deficiency is partly supplied by the cold air from the plateaus lying westward, partly by southerly winds from the Gulf of Mexico, and partly by winds from the polar regions. It is necessary to remember that the distribution of pressure in April and May is not the same as in midsummer. In the region here considered, pressure is lowest in May, while in Utah, and probably also on the lower Colorado, it is lowest in July. In the spring the winds coming from the Gulf of Mexico will be more westerly than in summer, because their point of attraction is more easterly in the former season than in the latter,

To recapitulate: There is an extensive region in the southwest of the United States which has a common yearly period of winds, different as are its geographical features. It includes the extreme S. E. of California, Arizona, New Mexico, Southern Utah, Texas, Arkansas, the Indian Territory, Eastern Colorado, Eastern Wyoming, Southern Dacotah, Nebraska, Iowa, Kansas, and Missouri. The winds are S. E., S., or S. W. in summer, with a great ratio of the resultant in the south, diminishing

towards the north and east. In winter the winds are mostly N. and N. W. This region is equal to more than a million square miles, or about one-third of the United States, without Alaska.

See also Maps, Plates 8, 11, and 14, which clearly show this.

To the north and northeast is a country about which it is difficult to say anything definite. It includes the larger part of Wisconsin and Minnesota, Northern Michigan, Northern Dacotah, and Manitoba.

The percentages of the winds in this region are:-

				Sum	mer.							Wir	ıter.

In Northern Wisconsin the influence of Lake Superior is clearly seen. The winds are N. E. in summer, or from the lake; S. W. in winter, or from the land. It must be remembered that the five great lakes never entirely freeze over, and that the difference of temperature between the air over the open water and that over the land must be great. On the Canadian shore of Lake Superior (for example, at Michipicoten) the winds are N. E. in winter and S. W. in summer. In Northern Michigan the influence of the lake is not so clearly perceived. One of the stations, Marquette, is situated on a peninsula, having the lake to the east, while others have it to the north.

Yet it seems, on the whole, as shown on Plate 8, that the winds in this belt of country bear a resemblance to the monsoon region lying to the south, especially the prevalence of south winds in summer, which is seen as far as Winnipeg (49° 52' Lat. North).

The next region we have to consider is that between the Mississippi and the Appalachian range extending southward to the Cumberland range, and northward to Lakes Michigan and Huron, and somewhat beyond Lakes Erie and Ontario. The percentage of the winds is as follows:—

				Sun	ımer.							Win	nter.			
	Z.	N. E.	ы́	S. E.	vć.	S. W.	W.	N. W.	, z	N. E.	Бij	S. E.	νż	S. W.	W.	N. W.

In the greatest part of this region S. W. and W. winds prevail winter and summer. Looking at the isobar-chart (Plate 14) we see that at all seasons the pressure is higher in the region between the Gulf of Mexico and 35° N. L., and much lower near the lakes; hence there must be a south wind, which is converted into a S. W. by the influence of the earth's rotation. In summer and autumn the pressure is generally higher in the south Atlantic States than in the same latitude further west, and it would seem that S. E. and S. winds should be frequent from this cause. But the Appalachians do not permit an exchange of air in the lower strata, and, as the difference of pressure is but slight, S. E. winds will not often blow over the mountain-chains. In the winter-months pressure is generally higher west of the Alleghanies. Air is, so to say, heaped up by the prevailing S. W. winds. (See also Maps, Pl. 8, 11, and 14.)

The daily weather-maps of the Signal Office show that the centres of storms generally take a course nearly along the northern frontier of the United States, especially in the region of the lakes. The monthly bulletins, in which the tracks of the storm-centres are laid down, show this even more clearly. Besides this, very low barometrical minima are comparatively seldom west of the Mississippi, and the pressure generally diminishes in the centre of a storm the further it advances towards the east. The storm-tracks then lie mostly to the north of the region we are considering now. The winds during the passage of a storm must then be S. W. and W. When the storm-track is more southerly, cold and dry N. W. winds, in the rear of the storm, will be experienced. We see that in this region the N. W. is frequently observed, especially in the winter. The storm-tracks are, however, generally more southerly in winter than in summer.

See maps, Pl. 8 and 11, and for the motion of clouds, and the velocity of the winds, Plates 1 and 13.

The different parts of this region agree very well as to mean direction of the wind and even ratio of resultant: which generally amounts to about .30, which in winter is great enough for middle latitudes. In S. W. Illinois as well as in Kentucky the winds are much more southerly in summer than in the other parts of this region; which is easily accounted for by the proximity of these States to the trans-Mississippi region, where, as was shown before, the mean direction in summer is nearly due south. As there are no mountains separating the two regions, the country on both banks of the Mississippi being generally level, we must expect a gradual merging of one into the other. It was shown above that E. Missouri and N. E. Arkansas are also transition regions between the countries east and west of the Mississippi.

Another exception is Toronto. The winds here were recorded with great care, partly hourly during more than ten years, so that the difference presented cannot be explained by shortness of the period. The ratio of resultant is great only in winter, and it seems that a great part of the then prevailing N. W. are land winds. Lake Ontario is to the S. E. of Toronto For this reason we should expect S. E. winds from the lake in summer, but it seems that they do not prevail to a great extent, and that N. W. winds coming from over the colder waters of Lake Huron also reach Toronto. The motion of upper clouds at this place, as shown on Plate 1, nearly coincides with the course of the lower winds, being somewhat to the west in all seasons, the difference is greatest in spring, 61°, and least in summer, 7°.

The mean direction is more northerly in spring than in other seasons. The influence of the high pressure in the polar regions is seen in this, as also that of the lakes, covered at this season with melting ice. In the other seasons the mean direction is very nearly S. 67° W., or W. S. W. (See Plates 8 and 11.)

To explain the accordance of observations in this region among themselves, it must be remembered that it is comparatively old-settled, and the observations are numerous, especially in New York, Pennsylvania and Ohio, and some of them

long-continued; while in the territories the observations are mostly for short periods and the stations far between.

The lakes do not seem to cause monsoons of any consequence. There are, it is true, day and night winds on their shores, but they do not extend inland to a great distance.¹

The winds of the Atlantic coast of North America, from Labrador to Florida, have some common features, notwithstanding the great difference in latitude.

The general climatic features of the Atlantic slope are somewhat like those of the trans-Mississippi region, the winds of summer being more southerly than those of winter, the N. W. prevailing in winter, the S. W. in summer. The distribution of pressure is here, as elsewhere, instrumental in producing this system of winds. The region we are considering is open to the influence of the Atlantic, and as on other oceans a belt of highest pressure is seen to prevail there about 30° L. N., as shown on Plate 14. This would then cause southerly winds. But in winter this influence is counteracted by the higher pressure to the west, in the interior of the continent. Thus, the N. W. is prevailing in the colder months of the year. In summer there is nothing to check the influence of the higher pressure to the south, on the Atlantic Ocean and in the South Atlantic States. Therefore S. W. winds are seen to prevail in summer. (See Plate 8.)

¹ See the examination of the winds at the Western Reserve College, Ohio, at the different hours of the day, by Prof. Coffin, on p. 299.

Yet there is a difference between the N. and the S. of the Atlantic Coast, which will be best seen if we divide the Atlantic slope of the United States into three parts.

				Sum	mer.							Wi	nter.

New England	8	10	6	11	14	19	16	15	9	12	5	6	7	14	19	28
Virginia to Georgia	7	12	8	12	17	26	11	8	13	13	7	6	11	18	14	17

From this table it is seen that in summer the winds are more southerly in the S. Atlantic States than in the middle ones, while in New England the southerly direction is more prevailing. (See Plate 8.) In the case of New England this may be explained by the direction of the coast, which is nearly from W. to E. from Long Island Sound to Cape Cod, so as to have the ocean to the S. Thus the already prevailing southwesterly winds are strengthened by the relative position of land and sea.

In winter the differences are greater between north and south, the N. W. prevailing much more in New England than in the other sections, while in the south the winds are more equally distributed between the different points of the compass. The cause of this decrease of N. W. winds, the further we advance to the S., is the following: The N. W. winds on this coast are a movement of the air, tending to equalize the higher pressure in the interior of the continent with the lower off the coast. They are westerly winds deflected to the N. W. by the rotation of the earth. The difference of pressure in winter is much greater between the coast of Nova Scotia and the interior of New England than between the ocean near the Bermudas and the same latitude in the Southern States. This explains why the N. W. winds are rarer in this last section, in the ordinary course of events. (See Plates 8 and 14.)

During the passing of storms there is yet another cause: the storm-centres in winter pass often over New England from W. to E. In this case the winds to the northward of the storm-track will be in succession E., N. E., N., and N. W., these last appearing in the rear of the storm, being dry and intensely cold. In the Southern States the wind will then veer from S. E. to S. and S. W., sometimes to W., that is, become much more southerly.

This distribution of the winds explains also the extremely rapid increase of temperature from N. to S. on the Atlantic Coast of the United States, which is greater than anywhere else in a level country.

That the prevailing N. W. winds of New England and the middle Atlantic Coast are not merely local, caused by the difference of temperature of the land and sea, is proved by the strength of these winds. The relative prevalence of the N. W. is much greater, if we take into account the number of miles travelled instead of the number of observations only. (See Tables, Zones 9, 10, 11.) I give below the mean velocity, in miles per hour, for the three prevailing winds S. W., W., and N. W. in winter.

						S. W.	W.	N. W.
Eastern Pennsylvania, S	mithson	nian Stations	8 .			5.9	7.0 .	8.9

S. New Hampshire, Smit	hsoniai	n Stations				6.0	7.9	8.4
N. E. Massachusetts	4.6	66				4.5	5.0	7.5
S. E. Massachusetts	6.6	46-				5.6	7.7	8.2
Cape Cod and adj. isd's	6.6	4.6				10.9	10.9	20.0
S. E. Maine	44	66				6.9	6.6	11.1

This is also well shown by the map, Plate 13.

The great number and great strength of the N. W. winds at the top of Mount Washington is another proof of the great mass of air which moves in this direction. We have no observations during the winter on so high a mountain in the Southern States, but it is probable that we should not find the N. W. winds as prevalent there; it is more likely that the W. or S. W. would be the most frequent.

The mean direction of the winds in the four seasons is given in the following table, and also in plates 8 and 11:—

	Spring.	Summer.	Autumn. , Winter.	
Rigolet, Labrador Maine N. of 46° Montreal and St. Martins St. Johns, Newfoundland S. W. Maine N. New Hampshire Rhode Island S. Nova Scotia W. Massachusetts E. New York S. E. New York N. and Central New Jersey E. Pennsylvania N. E. Virginia S. E. Virginia S. E. Virginia S. Carolina, 38°—34° Georgia, 38°—34° Georgia, 30°—34° Georgia, 30°—33°	S. S1 W. 12 ² N. 77 W. 20 ³ N. 44 W. 12 ² N. 65 W. 14 ³ N. 77 W. 20 ³ N. 78 W. 17 ² N. 66 W. 21 ³ N. 63 W. 21 ³ N. 88 W. 22 ³ N. 80 W. 14 N. 55 W. 19 N. 68 W. 21 ³ N. 82 W. 19 S. 55 W. 07 S. 53 W. 18	N. 9° E	$\begin{array}{cccccccccccccccccccccccccccccccccccc$	70 21½ 28 31 35 37 33½ 29 29 29 29 21 21 11 23 11 23

The much more southerly direction of the wind in the five last regions, belonging to the S. Atlantic States, is seen at a first glance, while from New York to N. E. Virginia it is more W. S. W. Everywhere it is between S. and W. in summer, varying from nearly due south to nearly due west. The mean direction in the spring is nearly the same as in the winter, somewhat to the southward. The ratio of resultant is greater in the Middle and New England States than in the south, both winter and summer, but especially in winter.

A noticeable feature is the northerly direction in autumn in the South Atlantic region. It is at least 24° more northerly than in winter. This may be considered as an approach to the trade-wind region. The belt of highest pressure on the ocean has its most northerly position in September. As the indraught of air towards the continent, which produced southerly winds in summer, ceases in the autumn months, the air follows points of attraction further southward; that is,

flows towards the southern parts of the Mexican and Caribbean Seas, where the rainy season is at its height in October. (See also Plates 8 and 14.)

The British Provinces north of the United States have mostly the same system of winds as the latter country. This is especially the case in New Brunswick, Nova Scotia, and Newfoundland. Here we find the same conditions as in New England, that is, prevailing N. W. in winter, spring, and autumn, and S. W. in summer.

In Lower Canada the winds are influenced by the direction of the valley of the St. Lawrence, and therefore the S. W. are more frequent than they would be otherwise. The same is the case in N. E. New York, where most stations along the St. Lawrence show also prevailing S. W. winds. Labrador has N. W. winds, but the mean direction is more northerly in winter than in other parts of the Atlantic coast, and the ratio of resultant is extremely great. In fact, the N. W. wind in Labrador is so constant as to remind us of the winter monsoon of the eastern coast of Asia. As is the case there, this wind is caused by the great difference of pressure between the land to the W. and the ocean to the E., and, as this difference continues nearly all winter in the same direction, the wind is very constant from the N. W.

In summer the winds are from the N. and N. E. in Labrador, coming from the ice-laden seas in this direction. The frequency of N. W. winds, even in summer, seems to indicate that pressure is high in the interior of the continent also at that season. The great number of lakes and morasses, which are full of ice till the middle or end of summer, as also the long continuance of snow in the woods of Labrador, may be the cause of this relatively high pressure. (See Plates 8 and 14.)

A very instructive table, compiled by Prof. Coffin from observations at forty different places in Delaware, Southeastern Pennsylvania, and Southern New Jersey, shows the mean number of days of each month on which every wind blew. (See Table, Zone 11, p. 432.) The mean direction and ratio of resultant for this important region of the Middle States is given below.

January	N.	810	$\overline{\mathbf{W}}.$.28	July	S.	830	W41
February	N.	78	W.	.38	August	S.	64	W26
March	N.	83	W.	.30	September	N.	89	W31
April	S.	89	W.	.20	October	N.	88	W37
May.	S.	89	W.	.33	November	N.	79	W39
June	S.	84	W.	.33	December	N.	79	W44

Here, as generally on the Middle Atlantic coast, the change in the mean direction is slight, the wind being westerly in all months, and the difference but 38° between February, when the winds incline most to the north, and August, when the most southerly direction is reached.

A similar calculation of Prof. Coffin for forty-nine stations in New England, south of 45° L. N., shows the following. (See p. 360.)

January N. 57° W38	July	S. 47°	W41
February N. 59 W30	August	S. 41	W. $.25\frac{1}{2}$
March N. 65 W26	September !	S. 76	W. $.17\frac{1}{2}$
April West .14	October	S. 84	W26
May S. 48 W21	November 1	v. 61	W34
June S. 52 W32	December N	N. 59	W39

Here the change during the year is much greater than in the Middle Atlantic States, namely, 82°, the winds being more northerly in winter and more southerly in summer.

The region which is left to complete the temperate zone of North America is one of transition. It partakes of the character of all the surrounding areas. It includes the States of Louisiana, Mississippi, Alabama, and Florida. It is bounded on the west and northwest by the trans-Mississippi region, on the north by that of prevailing W. S. W. winds between the Mississippi and Appalachian chain, on the N. E. by the Atlantic region, and on the S. by the trade wind zone of the Mexican and Caribbean Seas. (See also Plates 5, 6, 8, and 14.)

The winds in the principal subdivisions are as follows:-

		Summer.					Winter.									
	ĸ.	N. E.	101	S. E.	vi	S. W.	W.	м. ж.	N.	N. E.	EĞ.	S. E.	ιώ ώ	S. W.	W.	N. W.

Louisiana	1 3 0.7 8 4 1 2 9 13 11 14 8	19 16 13 11 12 20 16 9 12 12 12 9	5 12 34 6 30 20 8 12 8 7 8	22 24 24 14 26 46 23 19 16 15 13 20	5 10 15 12 12 7 8 13 17 17 23	38 17 4 26 7 4 15 14 13 21 14 18	5 11 7 10 4 0.4 10 14 12 8 6 9	6 7 2 14 4 1 19 11 10 9 10 8	5 12 13 20 23 4 14 16 29 17 23 15	24 24 20 18 26 33 17 9 12 10 9 20	2 7 17 9 19 14 5 8 8 5 11 16	7 10 17 11 13 22 14 16 11 14 16	3 8 11 6 6 4 10 11 12 14 20	22 14 4 9 3 7 11 10 9 18 5 8	7 8 4 6 3 2 4 12 6 10 3 7	29 17 14 21 6 12 26 19 12 12 13 14

In this region a high pressure is to be found the whole year round, though the different subdivisions participate in it in a somewhat different degree, according to the seasons. It will be seen by reference to the isobar chart that the indraught towards the interior of the continent is so great in summer that the isobar of thirty inches remains east of the mouth of the Mississippi in this season and has even a more southerly position than in the winter, thus showing the great influence of the American continent on the pressure, as it was said before that generally the belt of highest pressure had a more northward position on the ocean in summer.

In the autumn, on the contrary, the isobar of 30 inches is found between 30°-35° L. N., while the interior of the continent has not yet regained the high pressure of winter, though the indraught has already ceased. At this season, as already remarked, about the southern Atlantic States, there is a nearer approach to the condition of the trade-wind region than at other times of the year. In Florida, as also in Alabama, Mississippi and Louisiana, the winds are decidedly northeasterly as far as 33° N. L. The air is drawn in towards the rainy belt of Mexico and Central America.

In winter the pressure is even a little higher in this region than in summer, but it is still higher to the northwest in the interior of the continent, and somewhat lower in the adjoining part of the Atlantic. The mean direction of the wind is then more northerly, or even northwesterly, as shown in the next table, and the maps, Plates 7, 8, and 14.

The Florida Keys and the Northern Bahamas belong approximately to the tradewind region, though, owing to the powerful influence of the continent, the winds are E. S. E. in summer. But this is also the case in the West Indies. In the other seasons the mean direction is nearly E. N. E., and the ratio great, though certainly not so great as further south, in the middle of the ocean, where it often attains from .80 to .90. The same may be said of S. E. Florida, only the winds are less regular, as is seen by the smallness of the ratio of resultant.

On the northern shore of the Gulf of Mexico, and to about 32° N. L., the winds are northeasterly in autumn, but the ratio of resultant is so small as not to warrant the calling of this a region of trade-winds. Pressure is high at this season, and a little lower on the Gulf, but the difference is very small. Besides this, the variations of pressure and temperature are great here in winter. When a belt of low pressure, a storm-centre, reaches the upper Mississippi, air is drawn from the Gulf to supply the deficiency. South winds, with high temperature and abundant precipitation, are the result. In spring and summer the Gulf States have southerly winds from the Atlantic and the Gulf. They then prevail to a greater extent than the northeasterly winds of winter.

I give below the mean direction for the year, and the ratio of resultant, to show how nearly balanced are the different directions, except in the Northern Bahamas, Florida Keys, and S. E. Florida, where the N. E. movement is well marked. (See also Plate 3.)

--	--	---	--	--	--

Except the last-named areas, we find a ratio of .20 in E. Louisiana, where it is due to the combination of the S. E. winds of summer, spring, and autumn, with the N. E. of winter. Then we have .18½ in the extreme N. of Miss., which belongs approximately to the zone of S. W. winds between the Mississippi and Appalachian chain. All the others have a very small ratio.

TROPICAL NORTH AMERICA AND WEST INDIES.

Mexico, Central America, and the West Indies are in the belt of trade-winds, but these are modified by the land-masses of North and South America. There is a great difference between the east and west shores of the first two countries. In the east, on the Atlantic Ocean, the heating of the continental areas increases the force of the trade-winds, or we may better say, induces monsoons blowing from the sea to the land in a direction but slightly different from that of the trade-wind itself.

On the western shore, on the contrary, the direction of the monsoon would be more or less opposite to that of the trades. If, as is the case near the tropics, the land is not warmer than the sea in winter, we shall have trades in this season near both coasts, the direction of the wind being nearly the same, and very different winds in the summer. This is the case in Mexico. We do not have observations on the western shore of that country, but can supply them by shipobservations taken on the Pacific Ocean, near the Mexican shores. (See Maps, Plates 3, 5, 6, and 7.) The percentage of winds is—

The N. W. winds of summer, the Mexican monsoon, as it is called, are seen to prevail especially between 20°-25° N. The cause of this may be that Northwestern Mexico, as also the adjoining part of the United States on the lower Colorado, is much more heated in summer than the zone between 15°-20°, which has at that time the regular tropical rains. As to Vera Cruz, it seems that the frequency of the N. winds is partly local, at least in summer, as the winds in the Mexican Gulf

are rather E. S. E. at that season. (See Plates 5 and 14.) The mean direction of the wind is given below for the last-named places, as well as for others in Mexico, the West Indies, and Central America.

(See also Plates 5, 6, and 7.)

In the West Indies the direction of the wind is nearly due east, and the ratio of resultant great, especially in Barbadoes. Here we have the real oceanic tradewind. About Havana the case is different. Cuba is sufficiently large to have monsoons, but as we have observations on the northern coast only, the result of the ascending currents of the summer in the interior of the island is to give additional force to the already prevailing E. N. E. winds. Observations on the south and west coasts of Cuba and San Domingo would show another distribution of winds. It is said by travellers that the Republic of San Domingo, in the eastern part of that island, is subject to the full force of the trade-wind, and the climate less hot, and healthier than could be expected, while Hayti, in the west, has not as regular trades and a hotter climate.

The eastern coast of Mexico has not as regular trades as the West Indies under the same latitude. In winter especially, the barometric range is great, and accordingly the winds variable; the sudden cold northers are especially noticeable in winter. They appear when pressure is very low in Mexico and Central America, and high in Texas and New Mexico. The appearance and course of the storm-centres, on which depend the Mexican northers, have not been investigated as have those of the United States. The northers extend far beyond the eastern coast of Mexico. The coast of Honduras, as far as Omoa, is subject to them, and they pass even over the low Isthmus of Tehuantepec to the Pacific coast. (See Map, Plate 6.)

On the north coast of Tchuantepec the mean direction of the wind is more northerly than in the rest of Mexico and the West Indies. This is no doubt due to the relative position of land and sea. In the city of Guatemala southwest winds

are as frequent in spring as northeast. This is the result of the great heat of this region, when, under the influence of the nearly perpendicular rays of the sun, a powerful ascending current is induced. The deficiency is supplied both from the Atlantic and Pacific Oceans, and, in the latter case, probably by air from the S. hemisphere. In the summer Guatemala has its regular rainy season, and the heat decreases. (See Plate 7.) On the Pacific Ocean, between 5°–10° N., near the coast of Central America, the movement of the air is already from the southwest, except in winter, showing the equatorial belt of lowest pressure to be about 10° L. N. In Costa Rica, nearly in the same latitude, in a plateau between the Atlantic and Pacific Oceans, the wind is still N. E.—that is, the regular trade. (See Plates 5, 6, and 7.)

The republic of Nicaragua lying in a depression between the Atlantic and Pacific Oceans, but with its settled part nearer to the latter, is said to have also very regular trade winds, so that its climate is thought to be one of the healthiest in the tropics.¹

The contrary seems to be the case in San Salvador, which has high mountains to the N. E. It is said to have the hottest climate of Central America. Probably there is a monsoon from the Pacific Ocean the whole year round, as under this low latitude there is little difference between the temperature of winter and summer.

SOUTH AMERICA.

There are very few observations on the winds of tropical South America, and, but for the regularity of the climate of these low latitudes, and the general descriptions given by scientific travellers, we would be at a loss to say anything definite about these countries.

The same may be said relative to barometrical observations, which furnish the key to the winds. They were made nearly exclusively on the coasts, and we do not know how far the extensive plains of South America modify the pressure of the air, if there is a depression there, at all comparable to that existing in the interior of Asia, Africa, and North America.

The want of accurate determination of heights would prevent our knowing it, even were barometrical observations more numerous. When we have barometrical observations from the temperate zone and see the pressure of summer fall much below that of winter, we judge that there must be a depression of some magnitude, even if, the accurate height of the station being unknown, we are unable to reduce the barometrical observations to sea-level. Not so in a tropical country, especially near the equator. The change of seasons can scarcely be said to exist, and, be the pressure higher or lower in the middle of a continent than on the oceans, it will not change perceptibly during the year.

Yet, summing up what we know of the physical geography of South America, we can hardly expect a very low pressure there, especially in the equatorial Amazonian region, as it is covered with dense forests, and the heating by the sun and

¹ See Squier, Nicaragua. Wagner, Naturwissenschaftliche Reisen, etc.

consequent ascending current cannot be much greater than on the ocean. We should rather expect a great barometrical depression in the treeless llanos of the Orinoco, and in the Pampas of the Argentine State, or in the Campos of southern Brazil, as shown on Plate 14. The last two regions being sub-tropical in greater part, the difference of season is well marked. We do not possess a single annual series of observations in the Pampas and Campos, but already Rio Janeiro, Montevideo and Buenos Ayres, as well as the stations of Chili, have a lower pressure in the warm months of the year.

In studying the winds of South America, the physical geography of this continent must be borne in mind. It is separated into two very unequal parts by the chain of the Andes, which runs near to the western coast. The mountains are so high, between 9° N. L. and 40° S. L. as not to permit any interchange of air in the lower strata. The eastern part of South America is generally level, having but two mountain systems of any importance, that of Brazil and that of Guiana, which were not inappropriately compared to the Alleghanies and the Canadian plateau in eastern North America.

These secondary mountain chains of South America have no great influence on the course of the winds, the whole extent of the continent to the eastern slope of the Andes being subject to the trade-winds, and the effect of the continental mass is here rather to intensify them.

This is especially the case on the Amazon, as stated by all travellers who have been there. They say the eastern wind is very regular, especially in the dry season, June to November, blowing at times with the strength of a gale. In the rainy season, especially on the upper Amazon, it is less regular, being frequently interrupted by calms and westerly winds. There can be no doubt as to the general accuracy of these facts, notwithstanding the want of long-continued observations.

We possess, also, an admirable description of the course of the seasons on the llanos (treeless plains) by A. Von Humboldt. The regular blowing of the trades, the clearness of the sky, and want of rain from November to May are particularly noticed there. The appearance of the rainy season is announced by shifting of the wind to S. W. The countries on the lower Orinoco (see Plates 5 and 6) are in the region of the northern trades, while the southern trades are already dominating on the Amazons.

There is a region between 1°-3° N. on the Rio Negro which seems to have prevailing calms and rain in all months, according to Humboldt and Wallace.

We have observations from Venezuela and Guiana, where the winds are as follows,²

¹ See Hartt's Geol. and Phys. Geogr. of Brazil; Bates, the Naturalist, on the Amazons; Wallace, Amazons and Rio Negro; Martens, Reise nach Brazilien; Herndon and Gibbon, Explorations of the Amazon.

² To prevent confusion I give the months of observations for the equatorial regions and the southern hemisphere. In the tables "Winter" always means December, January, and February, and "Summer" June, July, and August.

		June, July, August.						Dece	mber	, Jan	iary,	Геbru	ary.			
	Z.	N. E.	E.	zi zi	vi	S. W.	IV.	N. W.	z	Ä.E.	Eİ	S. E.	ν.,	S. W.	W.	N. W.
Northern Venezuela Catharina Sophia (Guiana) .	6 3	17 41	32	22 24	8 5	9 4	4 0.1	0.3	4	45 68	23 13	13 11	3	$\frac{6}{0.2}$	5 0.1	3 10

If N E, and E, are taken as the true representatives of the trade-winds, we see that they amount to 49 per cent. of all winds in the rainy season of Northern Venezuela, and to 68 per cent. in the dry season. In Guiana the trades are more regular, but it seems that it lies somewhat to the S, of the thermal equator; as December, January, and February are rainy months, the proportion of N. E. winds is then greatest. (See Plates 5, 6, and 7.)

In Tropical Brazil we have only the observations in Rio Janeiro, from which we deduct the PERCENTAGES given in the following table. To gain a better insight of the winds of this country, it is necessary to obtain observations made on the Atlantic Ocean near the coast.

	June, July, August.	December, January, February.
Lat. 190–210 S., long. 370–390 W long. 350–370 W	$ \begin{array}{c ccccccccccccccccccccccccccccccccccc$	$ \begin{bmatrix} 24 & 37 & 12 & 10 & 0 & 0 & 4 & 13 \\ 31 & 35 & 17 & 10 & 3 & 0.4 & 0.4 & 3 \\ 40 & 30 & 7 & 6 & 3 & 1 & 3 & 11 \\ 6 & 11 & 5 & 45 & 4 & 5 & 8 & 17 \end{bmatrix} $

On the Atlantic Ocean, near the coast of Brazil, the winds are more northerly in the rainy season, from December to February, or in the summer of the southern hemisphere. As to Rio Janeiro, the winds are influenced by the locality. The sea-wind (S. E.) generally begins at 9 A. M. and blows till sunset, while landwind and calms prevail night and morning.

The northerly direction of the winds off the coast of Brazil points to a barometrical minimum in the interior to the west of the Organ Mountains in the campos, as it should do, considering the great heat of the summer of the S. hemisphere, and the sparse covering of trees on the campos. Easterly winds are much more regular and strong in Northern Brazil¹ than on the coast near Rio Janeiro. In the latter region they are to be considered as sea-breezes rather than trade-winds.

In the La Plata States and on the Atlantic Ocean near them, the few observations we have give the following results in Percentages:—

¹ Burton gives a description of the strength of the E. winds on the lower S. Francisco River in "Highlands of Brazil."

The only observations of a year's duration made in the interior are those at Mendoza and Parana by Burmeister. He remarks as to Mendoza, that calms largely prevail, strong winds are very rare. In Parana, on the contrary, as on the coast of the La Plata States (Buenos Ayres, Montevideo) the winds are violent and atmospheric changes frequent and sudden. In this respect it reminds us of the climate of the Atlantic coast of the United States, though extremes of heat and cold similar to those of North America are never experienced. Two winds are especially noted as strong, the Pampero (S. W.) and the Su-Estada (S. E.). Though Parana is near to Buenos Ayres, the yearly period of the winds is nearly opposite. (See Plates 5, 6, and 7.)

The winds on the Straits of Magellan and on the west coast of S. America are very different from those of the eastern part of this continent, as shown in the following table of PERCENTAGES.

	June, July, August.	December, January, February.

The changes of the winds along the W. coast of South America are very regular and gradual; we can follow them for about 60° of latitude. In the extreme south, at Punta Arenas westerly winds are known to prevail especially from December to February, the warm season, while from June to August the number of N. and N. E. winds increases. These are land-winds. The mean direction is found to be northwesterly at all seasons, and the ratio of resultant great (see next page). We are here in the belt of westerly (or northwesterly) winds of the

¹ See his "Klima der Argentinischen Republik."

⁸⁹ July, 1875.

southern hemisphere, which are very strong and prevail all around the globe, especially from 40° to 60° S. In Puerto Montt these winds also prevail, especially in the cold season, June to August, while the quantity of southerly (cold polar) winds increases in December and February.

In Central Chili (Valparaiso and Santiago) we meet opposing winds in winter and summer. They are northerly in the cold season, southerly in the warm. This is a feature of the sub-tropical belt, which is especially well developed in the southern hemisphere, owing to the great extent of sea. But in Chili the winds are S. and S. W. from December to February, instead of S. E., the direction of the true trades. But this is easily explained by the high chain of the Andes, which does not permit an extensive circulation of air from the S. E. Besides this, air is drawn towards the land from the sea, which is to the westward. The seasons of Central Chili are in keeping with the sub-tropical winds; the summer months are rainless. The further we advance to the N. the greater time the polar winds (S. E., S., S. W.) blow and the longer is the rainless season. About 27° S. the rain ceases altogether, and this belt stretches along the coast of Bolivia and Peru to 5° S.

Santiago has regular sea and land winds, especially from December to March, as is shown by the tri-horary observations of the U.S. expedition under Capt. Wilkes. (See tables, Zone 25.) At midnight, 3, and 6 A.M., the winds are nearly N., from 9 A.M. to 9 P.M. they are nearly S.W. There is no gradual passage of one into the other, but a calm separates them in the morning and evening.

From the latitude of Central Chili to the Isthmus of Panama we can supply the deficiency of land-observations by those made at sea, near the coast. The prevailing wind in zones 25 and 24 (25°–35° S.) is S., especially in the last, where from that quarter more than half of all the winds blow. As we advance towards the north the wind is deflected to the S. E. by the influence of the earth's rotation. Between 5° and 10° S. (Zone 20) 90 per cent. of all the winds blow from the S. E. in the cold months of the year, giving the ratio of resultant 96. This gradual change in the direction of the wind is clearly seen on Plates 5 and 6. There is scarcely any trade-wind region in the southern hemisphere where they are so largely prevailing, and none in the northern hemisphere. Yet it is necessary to remember that the observations between 5° and 10° S, were taken further from the coast (85°–98° W.) than on the other parallels, and thus the proportion of S. E. winds is greater, and of S. less. The nearer to the coast, the less frequent are the S. E. winds, because of the proximity of the Andes on the E., and also because the land is here much warmer than the sea, on account of the extremely cold Peruvian current.

As we approach the equator, the S. winds again increase. Between 0° and 5° S. this increase is probably caused by the position of the cold marine current, which is deflected to the westward. But southerly winds here cross the equator, and are by the earth's rotation deflected to the S. W. Already between 0° and 5° N. there is a great proportion of S. W. winds, though the S. winds still prevail. The mean direction is to the W. of S., as shown on Plates 5 and 6. Between 5° and 10° N., even southerly winds prevail during nine months, especially from June to August. Only in the winter of the northern hemisphere the wind is N. W., and then even with a small ratio of resultant. The equatorial boundary of the northern

trades is thus seen to lie much N. of the equator in the Eastern Pacific. A great body of air is thus drawn in to about 10° L. N., and forms what is called a S. W. monsoon.

In other regions this is also the case; these S. W. monsoons reach a much higher latitude, about 12° N. on the coast of Africa, 17° N. in the interior of this continent, and even 30° N. in India. The following table gives the mean direction of the wind at stations in South America:—

	March to May.	June to August.	Sept. to Nov.	Dec. to Jan.

ATLANTIC OCEAN.

There are four wind-belts stretching across the Atlantic Ocean: the northern belt of westerly winds (principally S. W.); the northern trade-winds (N. E.); the southern trade-winds (S. E.); and the southern belt of westerly winds (principally N. W.). The first and the last of these are also called belts of variable winds in opposition to the constant trade-winds.

As the Atlantic Ocean is the great highway of civilized nations, its meteorology is better known than that of any other ocean. Though narrow when compared to the Pacific and Indian Oceans, the winds have sufficient space on the Atlantic, as it has very few islands, and no mountain-chain in its vicinity at all comparable to the Andes, which exercise so great an influence on the winds of the Pacific. This being the case, the winds of the Atlantic can be regarded as typical for the oceans. (See Plates 5, 6, and 7.)

The most important boundaries of the different systems of winds which occur in the Atlantic are the so-called outer (or polar) and the inner (or equatorial) limits of the trades. We give below these limits, according to the best source of information, the "Pilot Chart of the Atlantic Ocean," edited by the Meteorological Office in London.

The N. E. trade is much more to the north in the eastern part of the ocean than it is near the coast of America, and on the meridians of 55° to 50° W. its polar limit is still further south. We do not know accurately the equatorial limits of the N. E. trade; on these meridians they must, however, fall on the continent of S. America. The trade-wind belt seems to be more narrow about 40° W. than further eastward, except in the months from July to September.

The equatorial belt of calms and variable winds between the N. E. and S. E. trades is much broader and better marked in the eastern part of the ocean than in the middle. About 20° W. its mean breadth attains 12° in September, and even in January $3\frac{1}{2}$ °, while at 35° W. its breadth is only $\frac{1}{2}$ ° from January to March, so that frequently ships sail from one trade into another without passing through intervening calms. It should be observed that the direction of both trades is much

more easterly in the western than in the eastern part of the ocean. This will be readily seen by a reference to the map. (Plates 3, 5, 6, and 7.)

There are in other places much greater differences in the limits of the S. E. trade. Near the coast of America the winds are so irregular that the seamen do not consider them true trades, thus on the meridian of 30° W. the polar limit is set down at $16\frac{1}{2}^{\circ}$ S. to 21° S. according to the seasons. Near the coast of Africa (10° E.) the polar limit is south of 30° S. at all seasons. The S. E. trade advances much beyond the equator, except in the months of February, March, and April. In September it goes to 6° N. under 40° W.

The narrowing of the ocean in its equatorial part between Cape S. Roque in S. America and Cape Verde in Africa does not allow of a determination of the equatorial limits of the trade cast of 17° W. and west of 40° W., as it is known that the trades blow regularly only on the ocean.

The greater breadth, however, of the S. E. trade and its regularity near the equator are well known.

Along the coast of S. Africa there are prevailing S. W. winds the whole year. They exist also on the ocean. This African monsoon is caused by the rarefaction of the air in the interior of the continent, and, in the months from July to September, extends far beyond the equator, and occupies much of the zone between the S. E. and N. E. trade. Violent rains and thunder-storms are experienced at this season in this region of S. W. winds. There is no doubt that the S. E. trade is drawn far beyond the equator and gradually changed into a S. and then a S. W. wind. Having passed over a broad expanse of warm sea it is copiously loaded with vapor.

From January to March the Pilot Charts give the southern boundary of the S. W. winds at $2\frac{1}{2}^{\circ}$ N. and 15° W. It crosses the equator under 10° W.; 7° S. under the meridian of Greenwich; 10° S. under 4° E.; 20° S. under 10° E. Thus the belt of S. W. winds has the greatest breadth opposite the Bay of Biafra, and is much narrower North and south. From April to June the S. W. winds advance to 19° W. opposite Sierra Leone, while the boundary is nearer to the coast of Africa further southward.

From July to September the belt of S. W. winds occupies a great space off the west coast of N. Africa, between 17° and 32° W. and 6°-11 $\frac{1}{2}$ ° N. If the boundary were traced for every month, it would be found to coincide much more closely with the inner limits of the N. E. and S. E. trade; as it is, it is near enough, as the southern limit of the N. E. trade is 12° N. in September, near the coast of Africa, while the S. W. monsoons begin about $11\frac{1}{2}$ ° N.

It is important also to obtain a knowledge of the minor characteristics of the winds of the Atlantic, and this can best be done by studying the percentage of winds in the different regions of the ocean, as presented in the following table:—

North of the regularly-established trades, there is a zone with prevailing northerly winds, especially in summer, in the eastern part of the ocean, as seen on maps, Plates 5, 6, and 7. To this zone the Azores belong.

At Funchal, Madeira, the trade-wind is well established in summer, but northerly winds prevail in winter, though not regular enough to be called trades.

The northerly winds of summer between 30° and 40° N. are N. W. rather than N., showing the influence of the heated surface of Southern Europe and Northern Africa. The African monsoon is to be observed in Z. 17, N. 31, and on Plate 5; the prevailing wind is N. from December to February and S. from June to August.

Under the same latitude in the middle of the ocean the N. E. trade is well established at both seasons. (See Plates 5, 6, and 7.) In zone 18 (0 $^{\circ}$ -5 $^{\circ}$ N.) the S. E. trade begins to prevail.

Along the coast of Africa the S. E. trade is very southerly, especially from June to August in latitude from 5° to 15° S. It must be remembered that a cold marine current flows along this course, and, therefore, the conditions must be like what prevail near the western coast of S. America. (See maps, Pl. 5, 6, and 7.)

The wind blows along this cold current, while on the coast it blows from the cold current to the land; this gives the S.W. winds of South Africa from 0° to 20° S. The only difference from S. America is, that no such high chain of mountains rises here near the coast. The belt of land under the influence of the sea-winds is more

extensive in Africa, and more heated, the ascending current is, therefore, more powerful, and thus the air from over the cold current is attracted with more force. The mean direction of the wind in the tropical part of the Atlantic is as follows:—

	June to August.	Dec. to Feb.		June to August.	Dec. to Feb.
	Mean direction. Ratio of resulfant.	Mean direction. Ratio of resultant.		Mean direction. Ratio of resultant.	Mean direction. Ratio of resultant.

(See also Plates 5, 6, and 14.)

This table is so arranged as to show the corresponding latitudes north and south opposite to one another. It will be seen how much more regular are the southern trades, especially between 0°-15°.

In the northern hemisphere the trades are well established between 10°-15° N. in the middle and western part of the ocean; while near the African coast the winds are very variable, or better to say this latitude is divided in summer between the N. E. trade and the S. W. monsoon. In the corresponding latitude south, the S. E. trade is blowing regularly the whole year.

In latitude 5°-10° N. the S. E. trade is already established in the middle of the ocean from June to August and the African monsoon in full force further east. In the corresponding latitude in the southern hemisphere the trade is very regular. It is also blowing between 0°-5° N, with the exception of the months from December to February, when the mean direction is E. N. E. in the western part of the ocean, probably owing to the heating of a part of S. America, towards which the air is drawn from the ocean. (See also Map, Plate 6.)

The more easterly direction of the trades in the western part of the ocean is well marked, especially as concerns the S. E. trade. It is probably due to the rotation of the earth, which gives the winds more easting the further they advance.

There is no doubt that the winds of the Atlantic which blow near the coasts of America have traversed a great part of the ocean, and thus acquired more easting. As to the winds which blow in the eastern part of the ocean, they do not come from so far. The African continent rather attracts the winds than otherwise. It has before been shown that from 5° N. to 20° S. southwesterly winds blow the whole year on the ocean near the coast of Africa, as exhibited on Plate 7. Thus the trade which blows further to the west cannot come from Africa. It originates on the Atlantic Ocean itself, over the cold antarctic current flowing at some distance from the African coast.

Barometric observations are numerous on the Atlantic Ocean, and are important as giving us the key to the winds. (See Plate 14.) Unfortunately their tabulation and reduction is not all that can be desired. They are calculated without regard to longitude, and from 5° to 5° of latitude only. Thus we do not know the difference of pressure in the eastern and western parts of the ocean, although it must be great, especially in latitude from 20° to 35° N. and S. as shown by the great difference in the polar limits of the trades.

The Meteorological Institute of the Netherlands has undertaken the calculation of the barometric means of the Atlantic Ocean for every degree of latitude, distinguishing also, in the southern hemisphere, the outward and homeward voyages. This would give two sets of figures, one for the eastern and one for the middle part of the ocean, as the ships going to the East Indies take a course more to the westward, while on returning they go nearer to the coast of Africa. This expected publication will shed light on many obscure problems.

The most complete barometrical table for the Atlantic we now possess is published in the Pilot Charts. It is calculated from 5° to 5°, for every month. I have calculated from it the pressure of the two contrasting seasons, and have given in the following table the pressure observed on some islands and coast stations reduced to sea-level. (See also Plate 14.) The mean pressure is at 32° Fahr.

The polar boundaries of the N. E. and S. E. trades are marked by a high pressure (at 30° to 35° N. and at 20° to 30° S.), while the space intervening between the two trades—the belt of equatorial calms and variable winds, has a comparatively low pressure. It should be remarked that this low pressure remains on the northern hemisphere, changing from 10° to 15° N. in our summer and from 0° to 5° in our winter. The air from north and south is attracted towards this belt of low pressure, and, as the conditions of the tropics are very uniform, the winds also are very regular.

A comparison of stations in the west and east of the ocean will show that pressure is generally higher in the east (as in Madeira compared with Bermuda, in Christiansburg compared with Cayenne, and Cape Town compared with Buenos Ayres). This is an additional cause for the easting of the trade-winds near the American continent.

Pressure is extremely low in the higher latitudes of the southern hemisphere.

Between 55° and 60° it is lower than around Iceland, the lowest known in the northern hemisphere. The great permanence and strength of the westerly winds in the southern temperate zone is explained by this. (See Plates 5, 6, and 14.)

NORTHWESTERN EUROPE.

The islands to the N. W. of Europe have still the climate of the Atlantic Ocean. Only one of them, the largest and most northerly, Iceland, has some of the characteristics of the polar zone.

Near Iceland, on account of the heated current of the gulf-stream, is the lowest pressure of the northern hemisphere, and though it is especially marked in autumn and winter it is also conspicuous at the other seasons. As is to be expected from a country in such a position, the winds are very changeable, according to the shifting of the centre of lowest pressure to the north and south. The equatorial winds, S. W., and the polar, N. E., prevail in turn.

The Faröe islands have prevailing S. W. winds at all seasons. This is even more the case at the Shetland islands, and in Great Britain generally, as is shown by percentages in the next table.

There is little difference between the winds in winter and summer, from Faröe islands to southern England. A very slight one only can be detected in the greater number of W. and N. W. winds in summer. This applies not only to Great Britain, but also to the greatest part of northern and central Europe. It is due to two causes: First, the belt of highest barometer is more northerly in summer than in winter; and second, part of the air is attracted towards the depression of Central Asia.

In Great Britain the influence of the last cause is very small, as Central Asia is too distant, and the depression about Iceland so near, that it must act very powerfully even in summer. But the further we advance eastward the greater is the influence of the depression in Central Asia, and consequently the greater the difference between the direction of the wind in winter and summer. The next table gives the mean direction of the wind in Great Britain and Iceland.

(See also maps, Plates 5, 6, and 9; and map of Isobars, Plate 14.)

The ratio of resultant is less in spring than at other seasons. This is caused by the great increase of pressure in the Polar region, as has been shown before. N. E. winds are oftener experienced in spring than at other seasons.

I must further remark that the character of the winds in Great Britain and the adjoining islands is strictly oceanic *i. e.*, such as would be found in the same latitudes on the oceans. The relative position of the land and sea have scarcely any influence. This is due, first, to the great difference of pressure between north and south, and the great strength of the winds which is the result, so that local causes are comparatively unimportant; second, to the small extent of land, which, being besides pervaded by the influence of the sea, is neither much more heated in summer, nor much more cooled in winter than the surrounding ocean. (See Plates 9 and 12.)

The conditions of the Scandinavian Peninsula are very different. It is by itself a large body of land. Besides this, the high mountain chain rising near its western coast is a great barrier to the influence of the Atlantic Ocean on the interior. The result is a much more continental climate than could be expected from a country so near to the Atlantic Ocean.

In many respects the physical features resemble those of Alaska, where the contrast between the mild, equable climate of the coast and the excessive seasons of the interior is equally great. The winds of the Scandinavian Peninsula are shown in the two following tables; in the first by percentages, and in the second in direction.

In winter the whole coast of Norway has monsoon winds, blowing from the land to the sea, they are N. and N. E. at Christiania, S. E. at Christiansund, Bossekop and Hammerfest, and S. W. at Vardöe. In summer the conditions are reversed.

This was shown some years ago by the best authority in these matters, Prof. H. Mohn. He is of the opinion that the winds are deflected about 90° to the right of the direction they would have if they blew directly from the land in winter and from the sea in summer.

It must; however, be observed that in this result the number of observations alone is taken into account. The storms on the Atlantic coast of Norway are very violent, and the winds during their prevalence mostly S. and W. A south wind should prevail in Norway, taking into account the strength of winds and aside from local influences.

The high station of Dovre, in the interior, has largely prevailing S. winds. In this we see the influence of the high pressure to the S. and in the interior of the continent and of low pressure on the ocean to the W. and N. (See Plates 9 and 14.)

In northern Norway the winds are variable in summer and decidedly from the S. in the winter. In the latter season the general distribution of pressure in the

¹ Oversigt of Norges Klimatologi. See also Norsk Meteorologisk Aarbog.

surrounding countries, and the local monsoon influence, act in the same direction, as the land is to the S., the ocean to the N. In summer they counteract one another. Besides this, the character of the Arctic Ocean must be considered. It is traversed by a warm current, and at no time of the year do icebergs approach the coast of Norway. Even in the summer the temperature of its waters is higher than that of the air on the land. On such a sea a low pressure must prevail, and its monsoon-producing influence in summer cannot be compared with that of an ice-laden sea.

In northern Sweden the wind has also a southerly direction. The Gulf of Bothnia has but very little influence, being a small body of water and frozen to a great extent in winter, otherwise we would have northerly winds in winter, while the Arctic Ocean attracts the air so strongly that no other influence is to be considered in comparison. The S. winds of summer may be partly sea-winds.

In southern Sweden the winds are S. W. in the winter, and W. in summer. The influence of the low pressure in the interior of the continent begins to be felt here at the latter season. (See Plates 5, 6, 9 and 14.)

Bear Island, between Norway and Spitzbergen, lies N. of the warm current of the Gulf-stream. Accordingly the Polar current (E.) is largely prevailing in winter, while the winds of summer are more variable. Bear Island has a position very like that of Iceland, yet it is more clearly north of the warm ocean-current with its low pressure. Besides, at times the island is surrounded by extensive ice-fields, and the temperature sometimes sinks very low over them, and consequently pressure increases.

Iceland and Bear Island are important stations, proving the existence of prevailing polar winds N., N. E., E. in the waters north of Europe, and north of the warm current of the Gulf-stream, while all stations in the extreme north on the continent of Europe still have equatorial winds (S., S. W., W.). Thus, the division line between the two systems of winds is proved to be the belt of low pressure along the warm ocean-current. (See maps, Plates 5, 6 and 7.)

The winds of Spitzbergen seem to be more influenced by the relative position of land and sea than those of Bear Island. In winter they blow from the land, as is seen by the observations of Mossel-Bay, on the N. shore of the principal island, and Ice-Fjord on the S. shore of the same.

CENTRAL EUROPE.

Southwesterly and westerly winds prevail also in the rest of western Europe, that is, Denmark, Germany, the Netherlands, Belgium and Northern France.

This is evident from the following table of percentages:-

				Sum	mer.							Wii	ater.			
	N.	N. E.	ï.	S. E.	S.	S. W.	W.	N. W.	Ä	N. E.	E.	S. E.	υź	S. W.	W.	N. W.

This is still a region of the undisputed prevalence of westerly winds. What may be noticed in S. Sweden is seen here in nearly all the stations: the winds in summer incline somewhat to the N. W. Kämtz was the first to notice the opposite course taken by the N. W. and the S. E. winds on the continent of Europe, the first being most frequent in summer, the last in the winter.² This is caused by the contrasts of temperature and pressure of the interior of the continent, and of the Atlantic Ocean, the influence of the land being conspicuous in winter, that of the ocean in summer.

The S. W. winds are most numerous in Belgium and Holland, while this is less the case in southern Germany, where the W. winds prevail. This is partly caused by the influence of the Alps, which do not give free access to S. W. winds, while those from the west reach Germany without impediment. The direction of the winds in this region is given in the following table:—

		Spring.		Summe	r.	Autumn.	Winter,

¹ Result of forty years' observations, calculated by Haeghens, Annuaire de la Société Méteorologique de France.

² Repertorium für Meteorologie, v. ii.

(See also Plate 9.)

The N. W. winds of spring in most of the stations of Western Europe must be noticed, especially in stations near the coast of the Atlantic Ocean or the North Sea. The mean direction of the wind in summer is more northerly than in winter.

Central and Southern France, Northern Italy, Switzerland, and the western provinces of Austria are a border-land between two different systems of winds, southerly or westerly prevailing in the N. of this region, and northerly in the S. Still we must expect to find the winds very much influenced by locality in such mountainous countries. The following are the percentages of the winds in the countries mentioned.

			Summ	er.		1		Win	ter.

In Southern France N. W. and N. winds may be said to predominate, and not only are they the most frequent but also the strongest. They are known under the name of *Mistral*. As early as in 1861¹ Renou traced the isobaric lines of France, and showed that the highest pressure was found in the centre of the country near Limoges. Reduced to sea-level it amounted to 764 millimetres (30.08 inches), to the south it is less. In winter the temperature along the coast from Marseilles to Livorno is much higher than in the surrounding country, this being probably the cause of the lower pressure. (See Plate 14.) In summer the stony, treeless plains on the lower Rhone are so very much heated, as to attract the air of the surrounding country. It comes from the Atlantic, up the valley of the Garonne, as a N. W. wind, and descends towards the Mediterranean near Cette. It will be seen from the table that S. W. France has prevailing N. W. winds only in summer, while in winter southerly winds are frequent.

¹ "Annuaire de la Société Méteorologique de France," of that year.

The valley of the Rhone is another outlet for the air flowing towards the Provence. Here nearly all winds take a N. or S. direction, *i. e.*, flow in the direction of the valley; but the first are largely in excess, as is shown by the observations in Eastern France (from 45°-46° N.), and especially at Orange, where 62 per cent. of all the winds in summer and 54 per cent. in winter come from the N.¹ (See Plate 9.)

In the country further east the Alps seems to form a boundary between the prevailing W. and S. W. winds to the north, and N. winds to the south, at least in autumn and winter. This is caused, as has been previously said, by the relatively higher pressure of the country around the Alps, and the relatively low pressure on the Mediterranean. Unfortunately very few results of observations in Northern Italy could be obtained in the libraries of Washington, though many are known to exist. Besides, the observations of Milan and some other stations were reduced to the four components (N., E., S., W.), so that percentages calculated from them would not be immediately comparable to the observations of other places where eight directions are given.

The winds of Parma seem to show what takes place in the lowlands of N. Italy. In winter the prevailing wind is N. W., in summer nearly all directions are represented equally. Bologna seems to have monsoon winds W. (from the land) in winter, and E. (from the Adriatic) in summer. (See Plate 9.)

The stations of Switzerland S. of the Alps (Lugano, Bellinzona, Mendrisio) have largely prevailing N. winds, and a very great number of calms.

The admirable system of meteorological observations begun in Switzerland in 1864 has already given much information as to the winds on mountains and high passes. Of these, the observations on isolated mountains are most valuable, as on high passes the direction is often very much influenced by the surrounding mountains.

The direction on high peaks is generally the same as in the surrounding country, but the character is much more marked, one or two directions prevailing to a greater extent than at the foot of the mountains, and the intervening winds being less numerous.

The Chaumont is situated in the Jura Chain just above Neuchatel. Here we have already a slight prevalence of northerly winds in summer, which is continued in the valley of the Rhone, in Southern France. In the winter S. W. winds prevail to a very great extent on the Chaumont, much more than in Neuchatel and in Western Switzerland generally.

The winds of N. Switzerland are very like those of Germany, that is, westerly at all seasons, as shown on Plate 9, but rather S. W. in winter, and W. N. W. in summer. This is also the case on two isolated mountains of this region, the Uetliberg (near Zurich) and Rigi-Kulm, only the proportion of westerly wind is much greater on the mountains.

Chaumont, Uetliberg, and even Rigi-Kulm, are scarcely high enough to have

¹ Count Gasparin, Fournet, and Ch. Martens were among the first to draw attention to this prevalence of northerly winds in Southern France.

another system of winds than those of the plains and valleys of Switzerland. The winds of these isolated mountains rather give us an idea of what would be the case if local influences were eliminated. The high peaks of the Alps would show us a different system of winds. The following are the winds of Switzerland.

How much the winds are influenced by the locality on high mountain-passes, is seen by comparing the Julier and Bernina, both situated in E. Switzerland, but having nearly opposite winds, especially in spring and autumn.

The winds in winter are remarkably like in Northern and Western Switzerland, the extreme difference being only 21°. The ratio of resultant is greatest in the high stations, next in Northern Switzerland, and least at Geneva, where it is only 4. This last place is nearly on the border of the north winds in S. E. France. There are greater differences in summer, yet the mean direction is mostly between the N. and W. (See Plate 9.)

The western provinces of Austria have well-marked westerly winds in the N. (Bohemia, Moravia, Vienna), belonging, in part, to the same zone as those of Germany. This is also the case in the mountainous country (N. Illyria), and, as is the case in Switzerland, the high station of Hoch-Obir, 7016 feet above the sea, has a greater prevalence of westerly winds than the stations in the valleys.

On the Adriatic coast N. E. and E. winds prevail, being, as in S. France, directed from the land towards the sea. As there the prevailing wind is the strongest, so it is here.

The Bora of the Dalmatian coast is much feared by the seamen as a strong and cold wind. Another wind often blowing here is the Sirocco from the S. or S. E. It is originally a S. W. wind, but it is deflected by the highlands bordering the Adriatic, and takes a course parallel to the shores. The following are the directions of the wind in this region:—

				Spring.		Summer		Autuma		Winter

(See also Plates 5, 6, and 9.)

SOUTHERN EUROPE.

A belt of high pressure in the summer months is to be found about 40° N. in the Mediterranean. South of it we must expect to find N. and N. E. winds. Yet, as generally the pressure increases towards the W., that is, the eastern part of the Atlantic Ocean, the winds of summer are rather due N. and N. W. The air is attracted towards the Sahara Desert and other hot parts of Africa. The following are the percentages:—

	Summer.	Winter.
	M. W. W. W. W. W. W. W. W. W. W. W. W. W.

The Mediterranean region S. of 40° L. N. belongs most decidedly to the subtropical belt; that is, the summer is nearly or quite rainless, and the more we advance southward, the longer is this rainless period, extending to about six months at Malta and in Algeria, and to nine months in Lower Egypt, while the whole year is nearly rainless in the Sahara S. of 30°, as well as in Upper Egypt. In these conditions, especially when considering a region not deficient in vapor of water, as the shores of the Mediterranean, the absence of rain in summer indicates in our hemisphere very prevailing northerly winds. If even the wind-vane indicates southerly winds, we may be sure that they are merely local sea-winds, or winds deflected from their course by mountain chains, etc., provided that the places where they occur have the rainless summer of the sub-tropical zone. Now this is

the case in S. E. and S. W. Spain, where the winds are southerly in summer, coming from the Mediterranean and the Atlantic Ocean. Yet we know that scarcely any rain falls in summer there; for example, in Gibraltar no rain was observed in July and August, and only 0.1 inch in June, while $27\frac{1}{2}$ inches fall in the winter months. (See Plates 5, 6, and 9.)

In Lisbon, Malta, Corfu, and Athens, we see the extreme prevalence of northerly winds in summer, such as characterize the sub-tropical zone. Rome and Naples again have southwesterly winds in summer, but, according to the yearly period of their rains, they belong to the sub-tropical zone, though not so decidedly as Southern Portugal and Spain, as well as Greece.

The northerly winds of summer were known to the ancient Greeks. Aristotle mentions them under the name of Etesian winds. In their gentle regular flow, they resemble the trades, but their direction is more northerly than those of true trades.

The prevalence of northerly winds is not so decided in winter, though they are more frequent than others in the greater part of this region. They are, however, interrupted from time to time by southerly winds which bring rain.

The northern part of Spain does not belong to the sub-tropical zone, yet the N. E. and N. W. winds prevail in summer. For the northern coast of Spain it is a sea wind coming from the Bay of Biscay.

EASTERN EUROPE.

Northeastward from the Mediterranean region just considered, and southeastward from Germany and the western provinces of Austria, there is a region of prevailing N. W. winds—it comprises Hungary, Transylvania, the Danubian principalities, and S. W. Russia. The following table gives the percentages of winds in this region:—

						Sum	mer.							Wi	nter.	1				
			N.	N. E.	E.	S. E.	só	S. W.	W.	м. м	N.	N. E.	E.	S. E.	S.	S. W.	W.	N. W.		
Zone 9- Hungary, N. 343. N. 346. N. 347. S. W. Russia-	Buda. (Ofen)		28 45 12	13	6 8 2	5 4 21	9 28 0	10	6 2 8	29 5 42	28 42 9	12 4 7	5 9 3	9 4 22	30	13 5 11	4	3		
N. 351. N. 352.	Kischinev	:	14 22 25	6 12 5	11 7	6 20 10		9 7 5	5 2 10	50 13 13	22 22 17	7 16 14	2 16 10	11 13 9	9 7 15	12 8 10	6 7 13	3:		

The prevailing winds at both seasons are N. or N. W., and at Debreczin, Hermannstadt and Kischinev, they are very largely prevailing. The mean direction is as follows:—

				Spri	ug.	Summe	r.	Autumn		Winter.	
				Mean direction.	Ratio of resultant.	Mean direction.	Ratio of resultant.	Mean direction.	Ratio of resultant.	Mean direction,	Ratio of resultant.
Buda .				N. 280 V	V26	N. 230 W.	.321	N. 240 W.	.23	N. 140 W.	.21
Hermannstadt				S. 87 V	V15	N 34 W.	.30	S. 21 E.	.15	N. 57 W.	.18
Kischinev				N. 61 V	N25	N. 46 W.	.491	N. 58 W.	.25		.32
Odessa .				S. 37	E174	N. 71 W.	.06	N. 65 E.	.09		.08

The motion of clouds observed at Hermannstadt gives in the summer a wind N. 56° W. mean direction, with a ratio of .39, and N. 59° W. in winter, ratio .39. So that the ratio is greater at both seasons than that of the lower current. At the first four stations, the prevalence of N. and N. W. winds is greater in summer than in winter. Besides in the summer the winds are more westerly, and more northerly in winter. The resultant for each month is as follows at Kischinev:—

	Mean direction. Ratio of resultant.		Mean direction. Ratio of resultant,		Mean direction. Ratio of resultant.
January February March April	N. 30° W. 30 N. 58 W. 33½ N. 61 W. 29 N. 46 W. 24	May June July August	N. 76° W24 N. 50 W43½ N. 46 W60 N. 41 W45	September October November December	N. 44° W40 N. 79 W21½ N. 66 W17 N. 37 W36

The months of March to May, October and November, have a much smaller amount of N. W. winds than the others. At Odessa and Hermannstadt where the prevalence of N. W. winds is generally less marked, the mean direction is not between N. and W. in spring and autumn. That it should be N. W. in summer in Odessa, though with a small ratio, is a proof of the strength of the N. W. current in these regions. (See Plates 5, 6, 9, and 14.). Odessa is so situated that it should have S. W. monsoon winds in summer, as the Black Sea lies southward, and the steppes around the city are highly heated at this season. Yet this monsoon is but slightly felt, while sea-winds are prevailing in the coast stations of the Crimea and on the shores of the Sea of Azof.

A glance at the map (Plates 5 and 6) will show that the region now considered has a great similarity of position with that of southern France. The relation to the N. W. part of the Mediterranean in the last-named region, and the N. W. part of the Black Sea in this, is the same. The result, prevailing N. and N. W. winds, is also similar.

I have already defined the position of the belt of high pressure which I called the great Axis of the continent, which reaches in winter from Southern Siberia to Central France, through a great part of the Asiatic-European Continent, and also influences to the Caspian, Black and Mediterranean Seas. (See Plate 14.) On these regions the temperature is much higher, and the pressure lower, than on the continents to the north. This gives prevailing easterly winds on the northern shores of the Caspian and Black Seas. Now the regions we are considering are in a

peculiar position towards the southern scas. They are separated from the Mediterranean and Adriatic by some high ranges of mountains. If we suppose a N.E. wind at Kischinev, directed towards the Adriatic, it would have first to pass across the Carpathian mountains, and then, besides others, over the high chains of Dalmatia and Bosnia, towards the Ægean Sea where there are also mountains—the Balkan chain, leaving but the narrow aperture of the Bosphorus, where a N.E. wind prevails during the year.¹ Hungary even, though situated to the S. W. of the Carpathian, has high mountains intervening between it and the Adriatic. Toward the Black Sea the air can arrive more easily along the Danube. There are also some low though narrow passes between Transylvania and Wallachia. Thus we have here a region of high pressure in winter, with a comparatively warm sea lying towards the E. and S. E. The movement of air in this direction is easy. The result is a prevalence of N. and N. W. winds, as shown by the map, Plate 6.

In the summer the pressure is low in the interior of the continent and very high in the western Atlantic, between 30° and 40° N. West winds are the result of this. It was shown that they prevail in Germany and Switzerland, and the further eastward the more this must be the case. Thus we have the air from the Atlantic flowing over the Mediterranean as a north wind towards the depression in Africa, and over the Carpathian region as N.W. towards the Asiatic depression. (See Plate 5.)

In autumn, especially in September and October, the conditions change. Central Asia is already much cooled, pressure has risen there, but in Africa and western Asia there is still a region of low pressure, somewhat to the south of where it was in summer. This causes a more rapid movement of air southward and southwestward, even near the Black Sea, and a greater prevalence of N. E. winds than at other seasons, as shown by the maps, Plates 7 and 9. Pressure is very high in autumn on the northern shore of the Black Sea, and from thence the N. E. winds begin. This is the season when conditions very like to those of the trade-wind region occur here. And it is also a very dry season, the precipitation diminishing very much from June to October. (See Plate 14.)

The cause of the smaller prevalence of the N. W. winds in spring may be found in the low pressure which then prevails in the Mediterranean, while it rises in the Arctic regions. In April especially there is less difference in pressure in the northern hemisphere than in any other month. Thus the winds have a less decided character, and local peculiarities are of comparatively greater influence.

The steppes of south Russia have prevailing easterly winds during about nine months in the year. Only in summer westerly winds take the lead. This region is very different from the rest of Europe in this respect, as well as from the greatest part of the temperate zone of America, where westerly winds are the most frequent.

It was Wesselowski² who brought this fact before the scientific world, and proved it so abundantly that no doubt could be entertained as to its correctness. The winds are easterly in this region in winter, spring and autumn, because pressure is higher to the north and in the interior of the continent. The prevalence of easterly winds ceases in summer (or, more accurately, from the middle of May to the middle of

¹ See remarks of Dr. Dwight, p 369.

² In his work on the Climate of Russia.

August), on account of the barometrical depression in central Asia, to which the air is drawn from western Europe and the Atlantic Ocean. (See Plates 7 and 9.)

I give first the percentages and mean direction of the wind as obtained by Kämtz, being the means of 18 stations situated between the Black Sea and 53° N. L.

Year				***							S. 67 E.	.06

The mean direction in June and July is nearly opposite that in December and January, and the prevailing winds are opposite, being W. instead of E. There is no month of the year when the prevailing wind comes from another direction than W. or E.

From November to April the continental influence is seen to prevail, in June and July westerly winds from the Atlantic Ocean, as shown on Plate 5, while August and September have a much larger proportion of northerly winds than the other months, so that the resultant is N. of E. The same is the case in October in the southern part of this region (45°–50° N.) I have already characterized these winds as directed towards Africa and Western Asia, and not towards Central Asia, as in summer.

The small ratio of resultant in all months shows that this is a border region. Especially the stations between 50°-53° N. have this character. The winds are shown in percentages in the next table.

¹ Repertorium f. Meteorologie, v. ii. p. 293.

It is necessary to consider separately the different parts of Southern and Eastern Russia.

In the Crimea there are more easterly winds in summer than elsewhere. It must be remembered that this is a small peninsula, which can receive sea-winds from east and west. The high chain of mountains rising above the southern coast does not permit sea-winds from this direction to reach stations to the-northward, as Sevastopol and Simferopol.¹

The opposition of E. and W. winds is not only observed in the Crimea, but also in all that region of S. Russia between the Dnieper and the Don, and between the Black and Azof seas, and latitude 51° N. This is not the case in the steppes on the lower Volga and further east (Orenburg, Astrachan).

At Astrachan N. E. winds prevail in winter, and S. E. in summer. These last are monsoons from the Caspian Sea.

At Orenburg the prevailing winds are E. and N. E. in winter, and N. and W. in summer. The results of this station are especially valuable, the observations being made during twenty years and carefully discussed.² The mean direction in the different months is:—

Thus in the first four months the direction is nearly due E., the ratio moderately great in March; May to September have northerly winds, with a ratio in July equal to that of March, and S. S. E. in November and December. October stands by itself, having a mean direction from the W. S. W. The percentage of S. W. winds is 20.5, while it is but 18 in winter and 11 in summer. It seems that Orenburg is at this time to the north of the belt of high barometer then existing on the shores of the Black and Caspian seas. Lugan, Astrachan and other more southerly places have prevailing east winds, with little rain and a small amount of clouds. In the winter months Orenburg is then to the S. of the zone of highest pressure, as the winds are E. and N. E. (See Plates 5, 6 and 7.) The division-line runs between Orenburg and Samara, the last named place having prevailing S. W. winds in autumn and winter. The very northerly winds of summer are probably caused by the position of Orenburg just north of the dry and highly heated Kirghiz steppes. They are not found at other stations of Southern Russia nor in Central Asia, while northerly winds are more common in Western Siberia in the summer.

North of 53° in Russia the direction of the wind is about the same as prevails in Western and Central Europe, S. W. in winter, W. and N. W. in summer, as shown on Plate 9. The stations on the northern border of the steppes indicate this. The annexed table gives the percentages of the winds in Northern Russia:—

¹ For further details about the winds of the Crimea, see the elaborate memoir of W. Koeppen in the new Repertorium für Meteorol., vol. i.

² By A. Ovodof in the Memoirs of the Orenburg Section, Russian Geographical Society, v. i.

	Summer. Winter.	
		W. W.
Zone 7 N. 222. Gorki ¹ " 7. N. 101. Dorpat " 7. N. 95. Mitan and Riga " 7. N. 103. St. Petersburg ¹ " 6. Finland, coast stations ¹ " 6. Finland, inland stations ¹ " 6. N. 61(a). Kem, White Sea " 6. N. 63. Archangel, White Sea " 7. Gov. Vologda ¹ " 7. N. 107, 111. Moscow and Vladimir ¹ " 7. N. 124. N. E. Russia	$\begin{array}{cccccccccccccccccccccccccccccccccccc$	11 15 5 22 16 4

At inland stations between 54° and 58° N. (Gorki, Dorpat, Moscow, Vladimir) the direction is very like that which prevails in Germany and further west, that is, a decided prevalence of W. winds, more S. W. in winter, more W. and N. W. in summer. Further north, and aside from the influence of the sea (inner Finland, Government of Vologda, N. E. Russia) the winds are S. W. or S. even in summer. Thus we have the same conditions that prevail in northern Sweden.

At Riga and Mitau there are summer monsoon winds from the N., at the coast stations of Finland they are N. and W., at St. Petersburg W., at Kem on the western shore of the White Sea they are E., while Archangel again has N. winds in summer.

The existence of monsoon winds in so high a latitude is a remarkable fact. Kämtz was the first to show that the winds at Archangel had a monsoon character.² The mean direction at this place is:—

Summer, N. 18° E. .16:

Winter, S. 25° W. .30.

While at Kem it is:

Summer, N. 87° E. .24:

Winter, S. 87° W. .25½.

(See also Plate 9.)

A common trait in nearly all the stations of northern and central Russia is the frequence of S. E. winds in winter. In this the influence of the high pressure in the interior of the continent is seen.

NORTHERN AND CENTRAL ASIA.

The belt of westerly winds extends far into Siberia. Here, as in European Russia, we have a belt of high pressure in winter. North of 53° N. the winds are S. and W. in winter, between 50°-53° N. there is a zone of undecided winds, while S. of 50° N. they are easterly, and N. E. already on the lower Syr-Daria. The further we advance to the S. in this direction the greater is the prevalence of E. and N. E. winds in winter, as well as in spring and autumn. This is well

¹ Calculated by Wesselowski, in his work on the Climate of Russia.

² Bulletin Phys. Mat. de l'Acad. de St. Petersburg, vol. v. p. 301.

shown on Plate 7. This is a current of air from the belt of high pressure in S. Siberia towards the Caspian and Black Seas, as well as towards other regions further south, the Persian Gulf for example. Though largely prevailing, these E. and N. E. winds have not the constancy of the trades, as is proved by the rains which fall in central Asia. This may be better called a polar current, as a low temperature is brought by it into southern regions. The summer has prevailing N., N. W., and W. winds in Central Asia, this being the current of air setting towards the heated deserts of these regions with their rarefied air. (See Plate 5.)

North of the division belt from 50° to 53° the air flows towards the Arctic Ocean with its diminished pressure, in spring, autumn and winter. We know now that these winds are still prevailing in the valley of the Jenisei. (See Plates 5 and 6.) I give below the percentages of the winds in Western Siberia and Central Asia.

Zone 7. Eastern Ural ¹	H H H H 14 7 11 12 8 7 21 8 11 15 21 2	11 10 15 11 15	7 12 14		13 20 14 1 10 2 3 1 12 1	0 13 1	5 5 2 8 4 4 7 3	5 3	35 5	10 20 20 19	24 15 11 49	27. 16 10 5	M N 17

In all stations except the last four, the westerly and southerly current prevails in winter. This is a movement to supply the deficiency existing to the northward, on the Arctic Ocean. Yet it will be seen that the same wind is not the most numerous at all stations. We have S. E., S., S. W., and W. This seems to depend much on local position. Calms are very frequent in the interior parts of the continent, especially in cold winter weather. The winds are generally weak. Thus local influences are very conspicuous.

It seems that the direction of the valley has a great influence, the most frequent wind coming from the upper valley in winter; so, for example in Tobolsk the river coming from the S. E., the prevailing winds are from this direction. At Ichim, Barnaul and Krasnojarsk the rivers come from the S. W., and, as the local influence coincides here with the general conditions, the S. W. winds have an anomalous prevalence.

The only exception is at Omsk, where the rivers come from E. and S. E., and yet the S. W. wind is prevailing. This is probably due to the level position of this city.

¹ Mean of Catharinenburg Nijnii-Taguilsk and Bogoslowsk.

² The percentage for the winter is taken from older observations, published by Krivoschapkin in his work "Jenisseïski Okrug,"

A moderate prevalence of S. W. winds extending also to S. E., S., and W seems to be the real state of the case when local influences are eliminated. (See Plate 7.)

Until within a few years we knew next to nothing in regard to the winds in the basin of the Jenisei. Middendorff had expressed the opinion that the S. W. winds of Europe extended to the lower Jenisei, but there were not facts enough to sustain his opinion. The observations at Krasnojarsk showed that this was the case on the middle part of the river, while Jenisseisk, situated more to the N., has prevailing S. E. winds. This is caused by a change in the direction of the Jenissei from the mouth of the Angara; it flows from S. E., and, as at other points, the winds from the upper part of the river are prevailing.

It will be seen that the winds of the summer are very different from those of winter. The flow of air towards the depression of central Asia is the principal feature at this season. In Siberia we have the influence of the Arctic Ocean, which is principally felt. It is especially the Kara Sea with the Obi Bay, extending further southward than other parts of the Polar Sea, which we must consider. It must be remembered that the steppes and deserts of central Asia are not separated by any barrier from the Arctic Ocean, in the meridian of western Siberia, so that the air of the Arctic flows freely towards those countries with their high temperature and low pressure. In comparing the table given here for western Siberia with that for European Russia, it will be seen that N., N. E., and N. W. winds are much more frequent in the same latitudes in Siberia. In this the influence of the Arctic Ocean is to be seen, although westerly winds from the Atlantic Ocean also extend there. Pressure is not steady on the Arctic Ocean, its fluctuations are great even in summer, and when a storm-centre passes over it, the air from the Atlantic Ocean and southern Europe will be drawn in to supply the deficiency, as a S. W., W. or N. W. wind.

In summer central Asia has the same winds as western Siberia, W. and N. W., while in winter the difference is great. This is clearly shown on Plates 5 and 6. Semipalatinsk, being situated in the division of zone 50°-53°, has a system of winds intermediate between western Siberia and central Asia, the E. being the most frequent in winter, but southerly winds also occur.

Further south, on the lower Syr-Daria, at Taschkent and at Krasnovodsk (on the eastern shore of the Caspian) N. E. winds largely prevail in winter. That this is also the case in other parts of central Asia, where no long-continued observations have been made, is the report of nearly all the scientific travellers who have visited this country.¹

In the prevalence of easterly winds Central Asia resembles the steppes of Southern Russia, but there are two important differences. First, the winds are more northerly; second, they prevail to a much greater extent. In Central Asia the mean direction in winter is between N. and E., while in southern Russia it is between S. and E., Astrachan and Orenburg excepted, but these places are already on the border of central Asia. The reason of this difference of the two regions seems

¹ I refer, for example, to Khanikof, Basiner, Helmersen, Severtzof. 92 July, 1875.

to be that in central Asia the belt of highest pressure lies clearly north, while it is N. E. from southern Russia, where it is also at a greater distance further and its influence less felt. (See Plate 14.)

It was also Wesselowski who proved the existence of a zone of N. E. winds in Central Asia, though the observations at the time when he published his work (1857) were very few.

Below are the percentages of winds for spring and autumn:-

										Spri	ng.							Autı	ımn.			
							N.	N. E.	E.	S. E.	wi	S. W.	W.	N. W.	z.	N. E.	gi	S. E.	υż	S. W.	W.	N.W.
Eastern Ural							9	10	5	12		20	18	17	7	7	2	8,	8	23	24	
Kourgan .							15	9	11		15				17		10	11	13	11	16

Krasnovodsk	(E.	shore	of	Caspia	n)	٠	25	18	2	1	2	5	0	47								-

The proportion of westerly winds is larger in autumn than in winter, except in Krasnojarsk, where the great frequency of S. W. winds in winter has a local cause. Westerly winds are the most frequent at Jenisseïsk and Tobolsk, which is not the case in winter. The westerly winds in autumn are stronger than in winter, and local conditions not so important.

South of 50° easterly winds prevail largely. Pressure has risen in central Asia in autumn, and the region of high barometer is again found to the northward, yet not so much as in winter, as I have shown in the case of Orenburg. (See Plate 7.)

The Austro-Hungarian polar expedition has given us an insight into the winds of the region between 75°-80° lat. N., between Nova-Zembla and the newly discovered land of Francis Joseph. As the observations have not yet been reduced, I can but mention some remarks about the winds made by Capt. Weyprecht.¹ In the first winter, when they were drifted from near Cape Nassau to about $78\frac{1}{2}$ ° L. N. and 73° Long. E., they had S. E. and S. W. winds, in the spring the number of N. E. increased. At this time they had drifted to the westward. In the second winter (October, 1873, to May, 1874), they were about $79\frac{3}{4}$ ° L. N., and 59° Long. E., not far from Francis Joseph Land, and had largely prevailing E. N. E. winds (more than 50 per cent. of all winds).

It seems that in the polar sea, north of western Siberia, as well as in that north of Europe (Bear Island and Spitzbergen), the polar winds are far from prevailing to such an extent as in the same latitude on the North American continent and the islands north of it.

The observations in northern Nova-Zembla² show also a considerable number of

¹ Petermann's Mittheilungen, year 1875, No. 2.

² By Capt. Tobiesen, calculated by Prof. H. Mohn, see Petermann's Mitth. 1874, No. 5.

southerly winds in winter. The following are the percentages in winter on the northern coast of Nova-Zembla.

Here it seems that the winds blow from the land towards the partially open sea, with its low pressure and high temperature. By winds from the land I mean here local winds from the island itself, as also those from the cold Siberian continent.

We have seen before that prevailing westerly winds extend to the Jenisei. Farther north and east we have but very few observations. It seems that we have here the region of polar calms in winter. The number of calms increases towards the interior and N. E. of Siberia, till at last there can be said to be no prevailing wind. This is the region of highest pressure in winter, as shown on Plate 14, and of also the greatest cold. Here, unlike the American polar regions, the cold of winter is very permanent, and also high pressure. The cold is not brought by winds, but is generated on the spot by radiation.

I give below the percentages of winds as observed at some few stations.

							-					Sum	mer.							Wir	ıter.

In the first three places, situated in the vicinity of the Arctic Ocean, there is a decided prevalence of monsoon winds—from the land in winter, from the sea in summer. The mean direction at Nijnikolymsk¹ is in—

The direction of the winds in autumn and spring is probably nearest to that of winter, as may be expected from so high a latitude, where the land is colder than the sea a great part of the year. Thus the mean yearly direction is nearly S. The direction of winds on the northern coast of Siberia is about the same as on the shores of the White Sea (Archangel and Kem).

It is difficult to determine the reason of the frequent N. winds at Yacoutsk, if the air flows towards the Pacific Ocean and is deflected from its true course by the direction of the valley. At any rate, calms are the prevailing feature in win-

¹ The detailed calculations on the winds at this place were published by Spassky in his "Sibirski Vjestnik," year 1823. I have used here only the figures given by Wesselowski, p. 231, as I could not obtain the original.

ter. In the summer, winds from N., E., S., and W. are about equally frequent. It seems that in September and October, when westerly winds are so prevailing in Western Siberia, warm and moist currents of air from the Atlantic can extend to Yacoutsk. At least westerly winds reach the maximum of their frequency in October (20 per cent.). In this month the flow of air towards Central Asia has ceased, while pressure has not risen high enough at Yacoutsk to prevent westerly winds from the Atlantic. October is also the cloudiest month of the year, the amount of clouds being 6.9, while March has only 2.6. The number of rainy days then is also the greatest in the year.

At the mines of Nertschinsk calms are more prevalent than at any other station we know of. In the winter months 65 to 70 observations out of 100 show no movements of the air, and the recorded winds are generally weak. In spring and summer there are less calms and more strong winds. The basin of the Upper Amoor is thus shown to belong yet to the region of Siberian calms (in winter).

While this is the case in the lowlands and valleys, it seems that the conditions are different in higher regions of the atmosphere. At Mount Alibert, 200 miles west of Irkutsk, and over 7000 feet high, a very constant and strong W. N. W. wind is observed. This place was inhabited some years on account of rich mines of graphite, and it was necessary to erect a wall to protect the inmates from the violence of this wind. The mean temperature was found to be much higher in winter than in the same latitude in lower levels. This wind is probably the upper current flowing towards the Siberian pole of highest pressure. It has been supposed that such upper currents flowed towards all regions of high pressure, but this has been proved only for the polar limits of the trades.

MONSOON REGION OF EASTERN ASIA.

Southeastward from the coldest space of Siberia, towards the Pacific Ocean, we have the region of Asiatic monsoons. I have already explained the cause of the movement of air in this region, and it is only necessary to show how far it extends and how small our knowledge of the northern part of the monsoon region was until the last year. The percentages of the winds in winter and summer are given in the annexed table:—

				Sum	mer.							Wir	iter.

The mass of air which is drawn towards the Asiatic continent in summer is so great that the ordinary conditions prevailing over extensive areas of the oceans must be disturbed, as shown on Plates 5 and 14. As there is also a great mass of air drawn towards India and Indo-China, we must here consider Eastern and Southern Asia together.

The summer monsoon of Asia is a deflection of air already in motion, that is of part of the S. E. trade of the Indian Ocean and part of the N. E. trade of the Pacific Ocean. It is easy to prove this for the Indian Ocean, as the observations there are numerous and well discussed. This is not the case for the Pacific Ocean. Yet seeing a region of high pressure about 30° N. to the E. of China, it is impossible to conceive how the air from above it should not be drawn towards the heated Asiatic continent with its low pressure. Probably at the beginning of the summer monsoon, only the air over the nearest parts of the ocean is drawn towards Asia, and the circle extends as long as the pressure continues to sink over the continent.

The direction of the winds in summer on the coast of E. Siberia, as well as in China and Japan, shows that they cannot have come from the southern hemisphere, as they otherwise would have a direction from the S. W. as in India, and not E., S. E., or S. It seems that the air from the Pacific supplies the northern part of this region, from about 25° to 60° N. In Southern China the prevailing winds are already S. W., so that this is probably air from the southern hemisphere. (See Plates 5 and 6.)

As in summer the Asiatic continent attracts the winds, so, on the contrary, in winter a continuous stream of cold dry air pours out from it towards the surrounding seas. It takes mostly two directions: towards the depression in the northern part of the Pacific as S. W., W., and N. W. winds, and towards the equatorial region as a N. E. On the coast of E. Siberia, in northern China and northern Japan the winds are mostly N. W., in southern Japan and middle China they are N., and near the tropics they have a direction from the N. E.

The climate of the whole monsoon region is characterized by a great regularity. This is not only the case in the tropics, but also in the temperate zone. The periodicity of the change of monsoons is the leading feature, taking place at more or less fixed periods, with slight changes from year to year. The N. monsoon of winter is the dry time of the year, the summer or S. monsoon the time of clouds and rain. So, for example, at Pekin the amount of clouds is 2.5 in January and 6.3 in July, at Ochotsk, Ajan and Nikolaievsk (Amoor) 2.5 in January and 5.0 in August (an entirely clear sky = 0, an entirely overcast = 10). At Pekin the quantity of rain in July is more than fifty times greater than in January.

As this distribution of rain and clouds is caused by the monsoon, which brings the dry, cold air of the continent in winter, and the vapor-laden air of the sea in summer, thus causing the above-mentioned periodicity, we have means of judging of the character of the climates of this region even without having observations of winds. For a great extent of country, in China and Mantchooria as well as in eastern Siberia, we have no long-continued observations, yet the general character of the climate is known. Thus we must include in the monsoon zone, besides the tropical countries of India and Indo-China, all of China and Japan, Corea,

Mantchooria, the Amoor provinces and the western coast of the sea of Ochotsk, till about 60° N. L. (See Plates 5, 6, 7.)

As this last extension of the monsoon zone is not generally accepted, it is necessary to give some further details. I have already stated that on the last-named coast the cloudiness is double in summer of that of winter. The E. winds of summer and the W. winds which set in September or October lasting all winter are so well known to the inhabitants that they sail in July and August from Kamtschatka to Ajan or Ochotsk and return in September or October, having in each passage favorable winds. The rains have also a marked monsoon character at Ajan, only they are somewhat delayed, the largest amount falling in August and September. This is due to the great masses of ice in the sea of Ochotsk, which disappear only in the end of summer. So long as the sea is colder than the land, precipitation can not be copious, which is the case until August and September when the sea is warmer than the land.

As to the upper Amoor, the small amount of snow falling in winter and the abundant rains of summer also tend to show that this region is under the influence of the monsoons.

I give below the percentage of the prevailing winds of the different months at Hakodade (42° N. L.) and Nikolaievsk (53° N. L.) to show with how much regularity the change takes place in these northern latitudes, which were till now considered as not belonging to the monsoon regions.

India and adjacent regions have been long known to the Europeans as the classical country of the monsoons, though as we have seen their course is not less regular in China and Japan. There is a reason why the mind is more impressed with their regularity in the Indian Seas; owing to the low latitude, there is scarcely any difference of temperature between winter and summer. The change of the season from wet to dry and vice versa is then the only conspicuous feature in the course of the year. In China and Japan the difference of temperature is greater between the two seasons, and these changes more attract the attention. The inhabitant of a temperate zone finds here the habitual difference between winter and summer, and thus considers this climate as resembling his own, different as it may be in the course of the winds and the period of rains. The atmospheric pressure of the monsoon region is illustrated on Plate 14, the winds on Plates 5, 6 and 7.

SUNDA AND PHILIPPINE ISLANDS.

In the seas south of Indo-China there is a double system of monsoons. The S. E. trade crosses the equator in our summer, and gradually is changed to a S. and S. W. wind, while during our winter the N. E. trade crosses into the southern hemisphere, by and by assuming a direction from N. W. This last movement is caused by the heating and rarefaction of the air over Australia.

The Sunda Islands, being situated near the equator, are under the influence of both monsoons. The one or the other of them can bring rain, and this depends much more on local causes than on the situation north or south of the equator. The direction of the wind in this Archipelago and the surrounding seas is not only governed by the flow of air towards Asia and Australia (the great monsoons), but also by the heating and rarefaction of the air on the islands themselves, especially on the largest, Borneo and Sumatra. Even on the island of Java, narrow as it is, there are great irregularities in the course of the monsoons caused by day and night winds, at least at some seasons.

I give here the mean direction of the winds at Batavia, from the elaborate discussion of the observations made at this place by Dr. Bergsma, director of the Observatory.

	Mean direction. Ratio of resultant.		Mean direction, Ratio of resultant.		Mean direction, Ratio of
January February	N. 87° W64 N. 83 W61 N. 27 W14 N. 85 E11	June July	N. 66° E28 N. 60 E36 N. 59 E35 N. 58 E29	September October November December	N. 21 E23 N. 3 E02 S. 62 W25 S. 85 W74

It will be seen that the west monsoon (in our winter) is much more regular than the east monsoon. Besides, in the last season, the mean direction of the wind is to the N. of E., while the S. E. trade should be expected.

This is probably due to sea and land winds, which blow more regularly and strongly, as this is a comparatively dry season.

I give next some percentages from this region, adding the Philippine Islands, where the extreme regularity of both monsoons is remarkable, while the Sunda Islands show more local deflections.

¹ An excellent sketch of the winds of Java, by Lieut. Jansen, is published in Maury's "Physical Geography of the Sea."

MONSOON REGION OF SOUTHERN ASIA.

Further west, on the Indian Ocean, and the Bay of Bengal, the following table shows the passage of the S. E. trade into the S. W. monsoon. I have given the result of observations on the eastern part of the ocean between 90° and 100° in percentages.

					Jı	ine to	Augi	ast.			De	cen	nber t	o F	ebru	ary.	
			N.	N.E.	Ë	S. E.		: :	N. W.	Ä.	N. E.	E.	S. E.	S.	S. W.	₩.	N. W.
Indian Ocean and Bay of Bengal, be """"""""""""""""""""""""""""""""""""	5 - 0 0 5 - 10 -	100° E. -10 S. -5 S. -5 N. 10 N. 15 N. 20 N.	2 7 2	8	20 6 1 0.4 0	50 14 4 4 1 0	24, 5	0 18 57 12 44	14 6 0.8	3 6 17 16 10 34	24 49 64	10 15 13	7 7	10 11 4 3 0 3		21 28 13 0.7 0 4	16 21 17 7 6 10

Between 5°-10° S. the S. E. trade prevails yet. From 0-5° S. these S. W. winds are already more frequent, which may be partly caused by the influence of Sumatra, although the S. and S. E. winds are also frequent. Between 0 and 10° N. the prevalence of S. W. is very large, but S. and W. are also well represented. North of 10° N. the S. W. winds prevail nearly to the exclusion of all others. In our winter the N. E. monsoon (or trade) largely prevails between 5° and 15° N. Between 0° and 5° N. the number of N. E. winds has decreased one-half, while N. and N. W. have increased in number, while from 0° to 10° S., west winds are the most numerous.

If we take a more westerly meridian, the result will be more clearly seen, as in the next table, and also on Plates 5 and 6.

						Jun	e to Au	gust.	Decem	ber to I	ebruary.
						Mean dire	ection.	Ratio of resultant.		ection.	Ratio of resultant.

Here we have from June to August the mean direction of the wind passing from S. 63° E. through S. 22° E. to S. 58° W., while farther north the mean direction becomes a little more southerly, probably owing to the influence of the continent. Still more regular is the passage of the N. E. trade into the N. W. monsoon of the southern hemisphere.

In the western part of the Indian Ocean, towards the coast of Africa, we have the following percentages:—

	June to August.	December () February.
Indian Ocean, 10°–15° S. 40°–45° E	$ \begin{array}{ c c c c c c c c c c c c c c c c c c c$	4 55 20 18 3 0 0 0 10 77 12 1 0 0 0 0

Here the S. E. trades prevail S. of 5° S.; between 0° and 5° S. there is a zone of variable winds, where S. E., S., S. W. and W. are most frequent, and north of the equator the S. W. monsoon is well established. From December to February the N. E. trades have an easterly direction between 10° and 15° N. They become more N. E. between 0° and 10° N., and between 5° and 10° S, N. W. winds are already prevailing.

Below the percentage of winds at some stations of India is given:-

	June to August, Decomber	December to January.									
	M. E. S. S. S. S. E. E. S. S. S. S. E. E. S. S. S. S. S. S. S. S. S. S. S. S. S.	S. W. W. W.

Zone 12. N. 185(a). Moultan " 12. N. 188(b). Lodianah and Dehra Door one 15. N. 35. Bombay, number of ols. " 16. N. 36. Madras " N. 34. Dodabetta, 8640ft., Neilgherrie	7 18 17 7 19 15 13 2 8 9 4 6 33 47 7 28 19 10										

There is less regularity in the winds of India, taken as a whole, than in Eastern Asia. Especially this is the case if we expect the summer monsoon to be everywhere S. W., and that of winter everywhere N. E. without regard to the position of the station towards the region of lowest pressure, and towards the ocean.

At Calcutta the monsoons must be N. and S., as the region of lowest pressure lies to the N. W. of this place, somewhere in the Punjab, as seen on Plate 14. In the N. W. provinces of India the winds of summer are rather S. E., while N. W. and W. winds prevail in winter. The latter is a current of air from the interior of the peninsula towards the sea, and has much in common with the N. W. winds of Eastern Asia. Farther to the N. W. at Lodianah and Dehra-Doon, we are nearly out of the monsoon region. According to Blanford the winter winds begin on the plains of Northern India, where the pressure is high at that season. They flow towards the seas to the S. W. and S. E.

At Bombay there is a very slight change in the direction of the prevailing wind,

¹ M. Blanford has well discussed the monsoons of Bengal and the adjoining provinces, and their relation to pressure, in "Reports of the Metcorol. Reporter of the Govt. of Bengal."
93 July, 1875.

it being N. N. W. in winter, and W. S. W. in summer. Yet Bombay is known to have very marked monsoon seasons, that is, scarcely any rain falls in winter, while it is profuse from June to September. At Madras the monsoons are from the same direction as on the seas in the same latitude, N. E. in winter, S. W. in summer. The relative position of land and sea has in this case a very small influence, otherwise we should have E. and S. E. winds in summer, W. and N. W. in winter. Madras is nearly due South of the lowest pressure in summer, and the difference is sufficiently great to give the prevalence and regularity of S. W. winds.

The winds at Dodabetta, a high station on the Neilgherries, S. W. of Madras, are peculiar; N. W. winds prevail in summer and S. E. in winter. This shows that the movement of air which is experienced near the sea-level does not extend very high. The mean direction in winter and summer is more than 90° different from that of Madras and other stations of India in low latitudes, and nearly the opposite of that of Calcutta, Central India and the Punjab, as shown by the following table:—

	Spring.	Summer.	Autumn	Winter.
	Mean	Mean	Mean	Mean
	direction.	direction.	direction.	direction.
	Ratio of	Ratio of	Ratio of	Ratio of
	resultant	resultant.	resultant.	resultant.
Colombo, Ceylon Madras Dodabetta Calcutta Bareilly Roorkee Sialkote, near Lahore Bombay	S. 30° W42	S. 58° W. 88	N. 63° W. 43	N. 37° W59
	S. 2 E74	S. 54 W. 85	N. 51 W. 24	N. 47 E68
	N 79 E69	N. 47 W. 81	N. 42 E. 32	S. 86 E62
	S. 1 E55	S. 13 E. 491	N. 4 E. 121	N. 21 W. 31½
	N. 51 W33	S. 64 E. 35	N. 11 W. 12	N. 52 W41
	S. 87 W11	S. 42 E. 29	S. 9 W. 06	N. 67 W18
	N. 86 W22	S. 51 E. 49	S. 80 W. 47	N. 85 W34
	N 58 W62	S. 70 W. 78	N. 25 W. 37	N. 5 W64

Thus, on a great part of the continent of India, the motion of air is towards the centre of lowest pressure in the Punjab, as also seen on Plates 5, 6, and 7, while at Dodabetta, 8640 feet high, it is from the Punjab. It seems thus, that the rarefaction of air does not extend to very high regions. In the winter, on the contrary, air moves from N. W. India towards the Bay of Bengal, and in the opposite direction at Dodabetta.

Blanford considers the winds at this high station as somewhat similar to the return-trade or westerly winds blowing over the trades on tropical seas.

At Roorkee the mean pressure in January is 29.15, in June 28.62, difference 0.53 inche, at Dodabetta it is 22.18 in January, 22.09 in June, difference 0.09 in.

It is also seen that the summer monsoon is shorter in the northern part of India, spring and autumn having the same direction of the wind as winter, only the ratio of resultant is smaller. At Calcutta and Madras the S. winds are already established early in spring, while at Colombo, Ceylon, still farther south, spring, summer, and autumn have the same direction of wind. (See Plate 7.)

The dominating winds seem also to be the strongest. So, for example, at Bombay, the greatest mean velocities were distributed as follows: in May S. S. E. 16.5 miles an hour, June S. S. E. 27.5 miles, July W. S. W. 21.4, August S. W. 17.0, December N. N. W. 13.9, January N. N. W. 14.1, and in February N. W. 14.6.

South of the tropic in India the pressure is so much lower on the land than on the sea, that the yearly direction is S. or S. W., with a ratio of resultant, increasing towards the south.

Calcutta S. 2° E. .16½. Madras S. 30° W. .18. Colombo S. 61° W. .29.

Farther to the west, at Bombay, the mean yearly direction is N. $45\frac{1}{2}^{\circ}$ W. .42, thus showing a flow of air from the west, or a much higher pressure on the part of the Indian Ocean between India and North Africa, as also seen on Plates 3 and 14.

As will be shown hereafter, the prevailing winds are also W. and N. W., in Syria and Mesopotamia, especially in summer, but to a less degree in the mean of the year.

WESTERN ASIA.

In Western Asia, that is, in the part of the continent west of India and south of the Caucasus and Black Sea, numerous observations of the winds have not been made. Yet they are needed much more than, for example, in India and eastern Asia, because the latter countries have such a marked climatic type that a very few stations are enough to give us an idea of the whole. Not so western Asia, where there is no regularity and uniformity of climate, and where many local causes have influence on the wind at the few stations established there. The following table gives the PERCENTAGES of winds in this region:—

PERCENTAGES

	Summer. Winter.	
		N. W.
Zone 13. N. 214. Mosul " 12. N. 183. Bagdad " 12. N. 180. Beirut " 12. N. 179. Jerusalem " 13. N. 212. Aleppo " 11. N. 221. Isl. of Ashur-Ade, near Astrabad, S. E. Caspian " 11. N. 217. Aralikh " 10. Constantinople	$ \begin{array}{cccccccccccccccccccccccccccccccccccc$	10 16 15 15 16 23 15 41 8 39 6

The first five places have extremely prevailing west and northwest winds in summer—a flow of air towards the depression in Central Asia. At Beirut, Jerusalem and Aleppo, they may be said to be sea-winds, but this is certainly not the case at Mosul and Bagdad, as the Persian Gulf lies to the S. E. of them. Here the winds in the summer are directed from the land to the sea, as also during the same time at Madras. This movement is thus shown not to be local, caused by the difference of temperature between land and sea, but it is part of the general movement towards the depression in Central Asia and India. The meteorological effects of these winds in Syria and Mesopotamia are very different from those of the S. W.

monsoon in India—they bring dry and clear weather. This is easily explained by their origin and direction: in Mesopotamia they come over the land, in Syria from a colder part of the sea.

In all these stations there is a greater number of N., N. E., and E. winds in winter than in summer, Jerusalem alone excepted. In this the influence of the high pressure of the more northerly parts of Asia is clearly seen, and is also shown by Plate 14. Yet it seems that the higher pressure prevailing over northern Africa in that season, and generally about 30° N., has also an influence on the winds: the S. W. in Jerusalem and Beirut, and the W. at Bagdad have probably this origin. Generally the winds are not as constant in winter as they are in summer.

On the Caspian local monsoons prevail. Ashur-Ade, an island in the S. E. corner of the sea, has E. winds in winter and W. in summer. Lenkoran, on the western shore, has prevailing S. E. in summer and N. W. in winter.

At Aralikh at the foot of the Ararat, the prevailing winds are S. E. in winter, that is, from the interior of the continent, and W. in summer.

On the eastern shore of the Black Sea, we see again very strongly marked monsoon winds, from the land (E) in winter, from the sea (S. W., W.) in summer. The winds here are nearly opposite to those of Lenkoran. It will be noticed that the monsoon character is more marked on the eastern shore of the Black Sea; the reason is, that here the local monsoons correspond to the general movement of the air over this part of Asia, while at Lenkoran they are nearly opposite to it. (See Plates 5 and 6.) The winds of Tiflis are too much influenced by the locality to show the general flow of air over the region.

Trebizonde has prevailing E. and N. W. winds in winter and summer. The country around is very mountainous, and nearly all winds come from one of these two directions. It is very difficult to reach a conclusion on the character of the winds when they are so much influenced by locality.¹

It seems that the winds at Erzeroom are also much influenced by locality, as it is situated in a rugged mountainous country. It may be that at this elevation, above 6000 feet, the winds are not the same as in the lowlands. E. and N. E. are prevailing here the whole year. I must remark that at all continental stations of western Asia, north, east, and south of Erzeroom the winds are either W. or N. W. in summer (Tiflis, Aralikh, Ooroomiah, Mt. Seir, Bagdad, Mosul, Aleppo). (See Plate 5.) This is with the exception of Alexandropol, which is also a high station (4800 feet) on the plateau of Armenia. At Constantinople the local position is such as to allow scarcely any other wind than N. E. and S. W.; the N. E. are dominant. But it would be rash to conclude that this is the trade-wind. We have seen that to the N. W. of the Black Sea there is a region of prevailing N. W. winds. The country is so walled in by mountains, especially south of the Black Sea, in Asia Minor, that the air must escape through the narrow aperture of the Bosphorus; thence the N. E. winds at Constantinople.

Some meteorologists think that the "trades" are dominant in Western Asia, reaching as far as Constantinople. This idea is founded on the observations at Erze-

¹ See the remarks of the observer at Erzeroom, Rev. N. Benjamin, in the tables, p. 371.

room, Trebizonde and Constantinople, given by Prof. Coffin in his "Winds of the Northern Hemisphere." I have shown that so far as the summer is concerned, we cannot accept this conclusion. At Constantinople and Trebizonde the winds are too strongly influenced by locality, and Erzeroom is too high to warrant an application to the lower regions. Besides this, at other stations, better situated, the winds are westerly. As to the winter, and especially the autumn, I have no difficulty in admitting prevailing N. and E. winds in Trans-Caucasia and Asia Minor, but these are winds which have not the constancy of the trades. (See Plates 6, 7 and 14.)

I should say that the erroneous opinion in regard to the extension of the trades cannot be imputed to Prof. Coffin. The number of stations was so small when he wrote his book (1853), that he wisely refrained from a conclusion.

NORTH AFRICA.

In Africa north of the equator the winds are as given in percentages in the following table:—

			Jun	e to	Aug	ust.				De	cemt	oer t	o Fe	brua	ry.	
	×	N. E.	ВÍ	S. E.	νά	S. W.	W.	N. W.	N.	N. E.	ы́	S. E.	7/2	S. W.	W.	N. W.
Eastern Africa— Zone 12. Alexandria and Port Said " 12. Cairo and Ismailia . " 13. N. 73(a). Suez " 13. N. 72. W. Egypt (Oases) " 13. N. 74. Upper Egypt " 14. N. 29. N. W. Nubia " 16. N. 25. W. and Central Africa— 12. N. 173. Tripoli 13. N. 71(a). Murzonk. 11. Northern Algeria* 16. N. 24(b). Goree, Cape Verde 16. Kouka, Bornoo 17. N. 33(a). Christiansborg, Guinea at 7 A. M. The same at noon	15 18 13 2 1 0	20	7 1 1 0	3 3 3	5 6 11	15 55	22	7 31 19 0 54 0.1	23	50	6	3 11 1 0 0	5 4 0 0,	16 0 0	0 0 0 0 4	1 21

To express the general features of the climate of Africa north of the equator, it may be said that N. of 17° N. northerly winds prevail the whole year, especially in the south of this zone, and south of 17° N. the winds are north in the winter and south in the summer. (See Plates 5 and 14.)

The division-line of about 17° is the zone of lowest pressure in summer. From the north air is drawn towards it from the Mediterranean, producing a wind similar to the trade in its constancy and other features. From the S. air is drawn in from the equatorial parts of the Atlantic and Indian oceans, and, coming over a great extent of warm sea, it brings clouds and rain as in the case of the Asiatic monsoon.

¹ For example, p. 137 of the "Winds of the Northern Hemisphere."

² Mean of Algiers, Oran, Mostaganem, Setif, Oum-Theboul.

We have seen already that on the Atlantic the division-line between the N. E. trade and the S. W. monsoon of the African coast runs about 12° N., the trade losing its regularity even at 14° N. in July. On the continent this line runs more north. The country to the north, having the whole year N. winds, is rainless, or nearly so; it is the Sahara or Great Desert; south is the Soudan, the country of Agriculture, where vegetation is more and more luxuriant the more we advance southward. This is caused by the longer continuance of the rain—They reach in the middle of the summer to about 17°, but in spring and autumn the division-line is more to the south, and south of this line there are southerly winds and rains.

The African traveller Rohlfs remarks that "in the beginning of July we traversed the Titimna or Great Steppe between 16° and 17° where a luxuriant vegetation is found. I noticed a remarkable change in the direction of the wind, instead of the N. E., E. and S. E. we had before, the S. W. was prevailing now. Later, when we came to the country with tropical rains (Kouka) the S. W. was still prevailing, though the rain-clouds came from the S. E." The woodland (Mimosa trees) began at about 15½° N. on the route he traversed. Very similar are the conditions in Nubia. Irregular tropical rains fall as far north as 19° N., further there is a country of prairies or savannah (openings) and still further south the woodland begins. The observations at Sennaar show very well the character of the climate in S. Nubia: N. winds in winter, S. winds in summer, both largely prevailing. (See Plate 7.) The remarkable frequence of calms when the sun passes the zenith is also to be noticed. So, for example, at Schimmedru, 18° 57' N., there were 37 per cent. of calms in April, 62 per cent. in May, and 47 per cent. in June. At Kouka, 12° 52', N. Rohlfs observed 46 per cent. of calms in July, 66 per cent. in August, and 51 per cent. in September. The sun is at its zenith at Schimmedru in May and at Kouka in August.

Gorée exhibits the change of monsoon in Western Africa.

Further S., on the coast of Guinea, the winds are from the same direction the whole year; this is the region of the S. W. winds. The daily period is very well marked the whole year, the winds being N. W. in the night and morning, and S. W. in the middle of the day.

On the shores of the Mediterranean the direction of the wind is not the same as in the desert. Especially in Algeria, where the N. W. is most frequent winter and summer. (See Plates 5, 6, and 7.) At the coast stations of Egypt (Alexandria and Port Said) W. and S. W. prevail in winter, and N. and N. W. in summer. There is a belt of highest pressure in winter, and, besides this, there are winds from the land to the sea in the cold season. Farther south, N. W. and N. winds prevail the whole year, as at Cairo, Ismailia, Suez.

¹ See Petermann's Mittheilungen, Ergänzungsheft, N. 25.

SOUTH AFRICA.

The winds of South Africa are very little known, except in the British Colonies in the extreme south.

It has been said already that along the west coast of S. Africa there were S. W. winds, that is, from the cold marine current towards the land. On the E. coast of Africa easterly winds prevail, although from December to February they are rather N. E., as the southern hemisphere is much heated then, and the pressure is higher on the north.

The mean direction and amount in percentage are as follows:-

*	June to August.	December to February.
Mozambique Channel, 15°-20° S	S. 17° E85	N. 31° E28
Indian Ocean, 20°-25° S., 47°-50° E	S. 84° E71	N. 67° E66
Port Louis, Mauritius	S. 61° E66½	N. 83° E47

	June to August. December to February	
Zone 22. N. 36. Madagascar		6 13 6 11 3 9 5 6 7 4 4 7

In Natal the general character of the winds is tropical, they are still E., but more regular in the summer season of the southern hemisphere (December to February).

In the Cape Colony the winds are regularly sub-tropical: polar (S.) from December to February, and equatorial (N., N. W.) from June to August. The regular yearly movement of the belt of highest pressure which forms the polar limit of the trades is seen here, in the extreme S. of Africa. In the warm season (December to February) it moves southward further towards the pole, so that the Cape Colony has then S. winds. In the winter (June to August) it recedes northward towards the equator. A reference to the map of isobars (Plate 14) will show that in July (midwinter) the pressure is very high in S. Africa, the isobar of 30.2 inches going from the Atlantic to the Indian Ocean, in latitude about 30°. In January, on the contrary, a pressure of 30 inches is found nowhere on the continent of S. Africa, nor on the Indian Ocean, but is restricted to the region of the cold marine current on the Atlantic.

INDIAN OCEAN.

I have given before some figures relating to the northern part of the Indian Ocean. Unfortunately we are far from knowing the winds of this ocean so well as those of the Atlantic. The limits of the trades especially are more uncertain. The position of the Indian Ocean is such, that only the S. E. trade is developed to its full extent, and in our summer, is attracted towards the heated continent of Asia, and, owing to the rotation of the earth, gradually becomes a S. W. wind. There is no equatorial belt of calms at that season, and a reference to the map of isobars, Plate 14, will show that pressure increases then from the polar limits of the S. E. trade, about 25° S. uninterruptedly to the continent of Asia. This is also the explanation of the S. W. Monsoon, which is only the deflected S. E. trade.

Even in our winter (December to February) the winds in the Indian Ocean are under the influence of continents. In the northern part the winds are N. W., that is the N. E. trade crosses the equator, and is drawn towards the heated continent of Australia. Nearer to Africa, the winds are N. E. at this season, also occasioned by a deflection of the trade-wind towards the tropical and sub-tropical part of Africa. Thus, on the whole, the Indian Ocean is more under the influence of the continents than the Atlantic. The following table gives the direction of the winds:—

										Jun	e to	Aug	ust.		1		De	ceml	oer t	o Fe	brца	ry.

"		N. 40.	Desola					16	2	0	1	0	16		34	- 5		2	0	7			15

There seems not to be a great difference between the limits of the N. E. trades in the eastern and western part of the Indian Ocean at all equal to that in the Atlantic. In Zone 25 (30° to 35° S.) we see a certain predominance of S. W. winds, which in the southern hemisphere correspond to the N. W. in the northern. In the North Atlantic Ocean there is a zone of prevailing northerly winds, rather N. W. than N. E. Thus in the Indian Ocean, especially near the coast of Africa (25° to 30° E.) we are already out of the S. E. trade, while S. and S. W. are yet prevailing. (See Plates 5, 6 and 7.)

Between 35° and 40° S, the westerly winds prevail very largely, and further south the number increases. Besides the large percentage of winds from this direction, they are also very strong, and in all respects prevail more extensively than in the corresponding latitudes of the northern hemisphere. It will be seen that the difference of pressure between north and south is here very great, the pressure being very low in the Antarctic regions, and high at the S, limit of the S, E.

trade. This produces the N. W. and west winds, while the great expanse of sea gives them additional strength. The only part of the northern hemisphere where the isobars are at all as close is the northern part of the Atlantic Ocean between 45° and 65° N. (See Plate 14.) Westerly winds prevail there, and are strong, but they cannot acquire full strength, as they have not so broad an expanse of ocean to blow over.

AUSTRALIA AND NEW ZEALAND.

The winds of Australia and New Zealand are largely modified by the influence of the continent. This is indicated by the following table:—

						Jur	e to .	Augu	st.		-		D	cem	ber t	o Feb	ruar	у.

The monsoon character of the winds in Australia is very marked. Somerset, on the N. coast 10° L. S., has still the regular monsoons of the Sunda Islands. From November to February the N. E. monsoon of India and China is drawn towards the southern hemisphere as a N. W. monsoon, and brings with it clouds and rain. In the other months the S. E. trade prevails very strongly, while the N. W. wind is said to be generally weak.

Further, in Queensland we have W. and S. W. from June to August (continental winds) and N. E. and E. from December to February (sea winds). Thus the air is drawn towards the continent in summer, when Australia is heated, and in winter, on the contrary, the wind blows from the land towards the sea, as also shown by Plates 5 and 6.

The colonies of Victoria and South Australia being situated on the south coast of the continent, the land and sea winds have not the same direction here as on the eastern coast. They have N. and N. E. winds in the cold season, and S. E., S., and S. W. in the warm. West Australia has decidedly N. E. winds from June to August, and S. W. from December to February.

Tasmania is somewhat under the influence of Australia, but here the winds begin already to assume the normal maritime character, especially on the small islands of Kent's group, near Tasmania.

⁹⁴ July, 1875.

In New Zealand the influence of the land is far from being as important as in Australia, and westerly winds largely prevailing as on the sea in the same latitudes (36° to 47° S.). There is a difference between the east and the west coast of the south island, separated as they are by the high and steep chain of the New Zealand Alps.

PACIFIC OCEAN.

As in the case of the Indian Ocean, the materials for the study of the winds of the Pacific are the percentage of the winds, as collected by Prof. Coffin, selections from which are given in the following table:—

			Jun	e to	Augt	ıst.				D	cem	ber t	o Feb	ruar	у.

What distinguishes the Pacific Ocean from the Atlantic is a less regular S. E. trade, which seems to be caused by the numerous islands of Polynesia. Many of them are high, volcanic, so as to intercept the wind for a certain distance. Another influence exerted by these islands is the local rains, which are produced by them, partly by condensation of the vapor brought by the trade; partly due to local calms and the ascending current. These condensations of vapor cause a lower pressure, and the movement of the surrounding air to supply the deficiency causes irregular winds.

¹ For the whole year.

Especially in the central and western part of the ocean (between 10°-20° S.), are these irregularities noted. It will be seen that in these parallels the S. F. trade is very regular in the Atlantic Ocean. (Plates 5 and 6.)

The inner boundaries of the S. E. and N. E. trade are given as follows by Kerhallet in his "Considerations Générales sur l'Ocean Pacifique,"

Months.			N. E. Trade.	S. E. Trade	Months.		N. E. Trade.	S. E. Trade.
January	٠		6° 30′ N.	5° N.	July		12° 5′ N.	5° 4' N.
February			4° 11′ N.	2° N.			15° N.	
March .			8° 15′ N.	5° 50′ N.			13° 56′ N.	
April .			4° 45′ N.	2° N.	October .		12° 20′ N.	3° 32′ N.
May .			7° 52′ N.	3° 36′ N.	November			
June .			9° 56′ N.	2° 30′ N.	December		5° 12′ N.	1° 56′ N.

These observations show that the belt of equatorial calms is always north of the equator. It seems that the figures given by Kerhallet are taken from observations in the eastern part of the ocean, near the American coast, where really the S. E. trade crosses the equator. The wide limits between the two trades in summer are caused by the prevalence of the S. W. monsoon on the coasts of Central and South America. (See Plates 5, 6 and 7.)

In other parts of the Pacific Ocean the equatorial calms seem to be nearer to the equator, and partly even south of it. According to the statements of numerous navigators the trades are also more easterly there, and often do not leave any calmbelt between them, so that a ship can sail from the one into the other trade without interruption, as was also stated for the western part of the Atlantic Ocean.

The northern limit of the N. E. trade is also in a comparatively low latitude in these parts, as shown, for example, by the observations at the Sandwich Islands. They seem to be already in the zone of variable winds in the winter, N. E. and S. W., the one being noticed about as frequently as the other. Rains are also frequent in this season, with S. W. winds, thus corroborating the testimony of the wind observations.

The system of winds along the western coast of America has been already discussed.

As to the middle latitudes of the southern hemisphere in the Pacific, the same may be said of them as of the same latitudes of the Atlantic, and Indian Oceans.

ANTARCTIC ZONE.

I give next some calculations from the extreme southern part of the Pacific and Antarctic Oceans, comprising the most southerly latitudes to which man has yet penetrated.

¹ See Pilot Chart of Atlantic, Pacific and Indian Ocean, edited by the British Admiralty. Unfortunately I could not obtain it in Washington, and thus have not the possibility of tracing the limits of the trades and monsoons according to the best source, as in the Atlantic.

" 34. By Sir James Ross			6 19 24 15 9 12 7 8				

The observations in these high southern latitudes are very conclusive; from the zone of the most prevailing westerly winds between 50° and 60°, we pass to a region of southerly and easterly winds further south. The latitudes at which these winds become prevailing are not the same in the whole Antarctic Ocean. South of Cape Horn W. and N. W. winds largely prevail between 60° and 62° S., and further south there are no observations in these meridians. Southeasterly winds are already prevailing in the meridians of the Atlantic Ocean, between 60° and 65° S., and also south of Australia, while again on the meridian of New Zealand 160° to 176° E., westerly winds are the most frequent. This seems to depend much on the currents of the sea. Where warm currents carry a high temperature further south, pressure will be lower there than in the same latitudes generally, and westerly winds will also extend further southward. Between 65° and 70° S. Lat., on the meridian of New Zealand, there is already a slight prevalence of southerly winds.

Between 70° and 78° S, the observations of Sir James Ross show this to be largely the case.

Thus the hypothesis of Prof. Coffin as to the prevalence of polar winds (S. and E.) is shown to hold good also for the southern hemisphere, notwithstanding the small number of observations we possess from high southern latitudes. As to the division-line from the W. and N. W. winds of the temperate regions, it cannot yet be traced with precision.

DESCRIPTION OF MAPS AND DIAGRAMS.

The direction of the wind on the maps, Plates 1 to 13, is indicated by arrows. For example, to indicate a N. wind, the head of the arrow is turned towards the south, and the tail towards the north. The direction indicated is not that of the prevailing wind, but the mean direction, the manner of calculation of which was explained in the beginning of this work. The length of the stem of the arrow, exclusive of its barb, is proportionate to the ratio of resultant, the greatest length being when the ratio is equal to 100, or when all winds come from the same direction. These maps were originally all drawn to a scale, in which one hundred per cent., as found in the tables, was intended to be represented by an arrow an inch in length; but, by the process of engraving adopted, it was found practicable to diminish the size of the maps somewhat, so that 100 per cent. equals two-thirds of an inch; for instance, on Plate 1, Zone 10, serial number 196, representing Eastern Pennsylvania, the arrow is 20 one-hundredths of an inch in length, corresponding to the tabular percentage 30 given on page 320. The more equally the winds are distributed around the horizon the smaller is the ratio, and also the shorter the arrow on the map. Where it is very small it indicates that there is no really prevailing wind. This is generally found on the boundaries of two systems of winds.

PLATE 1.

ANNUAL DIRECTION OF UPPER AND LOWER CURRENT IN THE UNITED STATES.

The mean direction of the wind, as observed by the wind-vane, is indicated by full arrows, and the direction of the motion of clouds by broken arrows. It will be seen that they very nearly coincide in nearly all regions of the United States. Generally the upper current is more purely west in all the regions east of the Mississippi, while the lower current has a more W. S. W. direction between the Mississippi and Apallachian Chain, as well as in the Southern Atlantic States, while in New England the winds are rather W. N. W. Near the Gulf of Mexico the arrows have a very different direction, but it will be seen that the arrows are very small, thus indicating an undecided prevalence of any wind. In some parts of Texas, also, the upper and lower current seem to come from different directions. In this map, as well as in the others, the figures relate to the serial number in the zone, and, by reference to the Numerical Index to Stations, given on pages 52 to 66, it is easy to find the name of the place indicated by each figure.

PLATE 2.

MEAN ANNUAL DIRECTION IN THE ARCTIC REGIONS.

It will be noticed that the mean direction of the wind is from the north in Greenland and Arctic America, and that the arrows are long, thus indicating very prevailing winds. On the northern coasts of Europe and Asia the winds are from the south, while Bear Island, between Norway and Spitzbergen, as well as Iceland, have prevailing easterly (polar) winds. In this map a dotted line is traced, and called "Southern limit of polar system." This is the same boundary as that traced by

the late Prof. Coffin on the maps of the "Winds of the Northern Hemisphere." In the mind of the deceased author this was the boundary between the prevailing polar winds of the Arctic regions and the equatorial (westerly) winds of the middle latitudes of the Northern Hemisphere. He traced it at a distance of 28° 20′ from an imaginary point which he called the "Meteorological Pole," and located in 84° N. lat. and 105° W. long.

PLATE 3.

MEAN ANNUAL DIRECTION BETWEEN 80° N. LAT. AND 56° S. LAT.

The general prevalence of westerly winds will be seen here in the middle latitudes of the Northern Hemisphere. Yet they are not always true equatorial winds, but incline somewhat to the north in some regions. On the tropical seas easterly winds largely prevail, as indicated by the length of the arrows. This is the region of the trade-winds which prevail more largely in the Southern Hemisphere than in the Northern. In the middle latitudes of the Southern Hemisphere westerly winds again prevail, and this to a large extent, while further south there are again easterly (polar) winds. In some parts of the globe, where monsoon winds prevail, the length of the arrow showing the mean annual direction is rather small (as in India, China, Japan). This does not come from an undecided character of the winds, but is caused by the nearly opposite direction of the winds in winter and summer. As they counteract one another in the yearly resultant, the ratio of the latter is small. A reference to Plates 5 and 6, giving the mean direction of the wind in summer and winter, shows that at each season the arrows in China, India, Japan, and the surrounding seas, have a great length, showing largely prevailing winds at both seasons.

Monsoon comes from the Arabic word Mausim, or wind of the season. We call monsoon regions those that have winds of nearly opposite character in winter and summer, each of these winds prevailing during some month of the year nearly to the exclusion of all others. On the greatest scale we see such winds along all the southern and eastern coast of Asia, and on the surrounding seas, the winds in the tropical part of this country being N. E. in winter and S. W. in summer, while further north, in the interior of India, China, Japan, and the Russian Amoor provinces, the winds are rather N. and N. W. in winter, and S. and S. E. in summer. Monsoon winds are caused by the mutual reaction of great continental masses and the ocean, and thus they are most prevailing where the greatest continent—Asia—approaches the greatest oceans—the Pacific and Indian. In winter the pressure of the air is high on great continents, and thus air flows out from there, while in summer, on the contrary, the land-masses being highly heated, an ascending current is produced and the continents and oceans adjoin, we see a tendency to produce monsoons. This is what Prof. Coffin has called monsoon influences, but not everywhere monsoon winds are dominant. Monsoon influences may be considered as small deflections from the mean annual direction in regions where no great differences in the mean direction of the wind in the different seasons are experienced, and thus this relative influence of land and sea is small. In monsoon regions, on the contrary, this influence is experienced on the largest scale,

PLATE 4.

MEAN DIRECTION IN THE FOUR SEASONS IN THE ANTARCTIC REGION.

The direction of the wind is here represented by broken arrows, thus:

A straight line drawn from the tail to the head of the arrow gives the mean annual direction. The sequence is always—spring, summer, autumn, winter. Thus the nearest part to the tail of the arrow indicates the mean direction and ratio of resultant in the spring, and the nearest to the head that of winter. As before stated, June, July and August are denominated "summer," etc.

PLATE 5.

MEAN DIRECTION IN THE SUMMER (JUNE, JULY, AUGUST) BETWEEN 80° N. LAT. AND 56° S. LAT.

This map shows the mean direction of the wind for the time in which the Northern Hemisphere is highly heated, while the southern has its winter. Very prevailing sea-winds (S. W., S., S. E.) along all the southern and eastern coast of Asia (the summer monsoon) are the principal features of the season. In Australia, especially on the northern coast, land-winds prevail. They are S. E. in the latter region. In other parts of the globe the difference between the direction of the wind in summer and that for the year is smaller. Yet, in the United States, there is a monsoon region north of the Gulf of Mexico, between the Rocky Mountains and the Mississippi. Southerly winds from the gulf are largely prevailing there. In Northern Africa northerly winds prevail to a larger extent than in the mean of the year. In the Atlantic the belt of the N. E. trade-winds has the most northerly position in the year, while north of it there are prevailing N. and N. W. winds to and beyond 40° N. lat. In Western Asia W. and N. W. winds prevail, this being a flow of air towards the barometric depression in N. W. India. In Southern Russia we see westerly winds at this season, the air flowing towards Central Asia.

PLATE 6.

Mean Direction in the Winter (December, January, February) between 80° N. Lat. and 56° S. Lat.

At this season the direction of the wind is nearly opposite to that observed in June, July and August in the monsoon region of Asia. N. E. winds prevail in Southern India and the Indo-Chinese Peninsula, N. and N. W. in the interior of India, and in China, Japan, and the Russian Amoor Provinces. The N. E. monsoon crosses the equator, appearing as a N. W. wind on the heated continent of Australia. In North America, Texas and the States to the north of it have prevailing N. and N. W. winds—a direction nearly opposite to that of summer. The S. W. winds which prevail the whole year in the temperate latitudes of the Northern Atlantic have now reached the maximum of their frequency and strength, blowing also in a great part of Europe. Southern Russia has prevailing east winds in winter. In Western Asia the westerly winds are not so largely prevailing as in summer. The trade-wind belt of the Northern Atlantic and Northern Pacific Oceans has receded to the southward.

PLATE 7.

DIRECTION OF THE WIND IN THE FOUR SEASONS BETWEEN 80° N. LAT. AND 56° S. LAT.

The general arrangement of this table is the same as for Plate 4. It will be noticed that generally the direction of the wind in spring is nearer to that of summer, and that of autumn to winter. This is especially the case in monsoon regions. In Northern Europe and the eastern part of the Atlantic Ocean the proportion of northerly winds is greatest in spring, giving, sometimes, a mean direction N. of W., while the other seasons have a mean direction S. W. or W. In other places the larger proportion of north winds has influence only in so far as to lessen the ratio of resultant, which is yet S. of W. In Southern Russia and Asia Minor the autumn has the largest proportion of N. E. winds, especially the months of September and October. Many places there have a mean direction nearly E. N. E. in autumn, while it is somewhat S. of E. in winter and W. N. W. in summer.

PLATE 8.

MEAN DIRECTION IN THE FOUR SEASONS IN THE UNITED STATES.

[See Explanation of Plate 4.]

Here, also, the mean direction of the wind in spring is nearer to that of summer, and that of autumn to winter. West of the Apallachian Chain, and north of 42° N. lat., there are more northerly winds in spring than in summer and autumn, while further south, and west of the Mississippi, southerly winds prevail already in spring. In the Southern Atlantic and Gulf States there are more northerly winds in autumn than in other seasons.

PLATE 9.

MEAN DIRECTION IN THE FOUR SEASONS IN EUROPE.

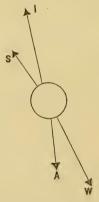

[See Explanations of Plate 4.]

The great extension of northerly winds in the Mediterranean in summer must be noticed. On this Plate are placed a few arrows, whose shafts are divided into twelve portions, corresponding to the successive months, beginning with March (spring), and ending at the barb with February (winter): Here, as in the preceding plate, may be observed the peculiar "S" shape of the curves, so regular a feature in the movement of the wind in the successive seasons, that it was the occasion that led Prof. Coffin to his investigation of the monsoon influences delineated in the following Plate.

PLATE 10.

Monsoon Influences in the Four Seasons between 80° N. Lat. and 56° S. Lat.

On this map there is a graphic representation of the forces which deflect the mean direction of the wind from its annual value at each season. Taking, for illustration, the monsoon influences at Easton, Pennsylvania, the manner of their representation is the following:—

Spring being designated by I, as the first season, summer by S, autumn by A, and winter by W. The opposite directions of the deflecting forces for both sides of the Atlantic Ocean is especially to be noticed. It was first pointed out by Prof. Coffin in a report to the American Association for the Advancement of Science, in 1848, and then embodied in his work on "the Winds of the Northern Hemisphere." The direction of the deflecting forces is from the S. E. on the coast of the United

States, and from N. W. on the Atlantic Coast of Europe in summer. Similar monsoon influences are at work on the coast of the White Sea and Arctic Ocean. In the real monsoon regions the deflecting forces are very powerful.

The mode by which these forces are ascertained is explained in the introduction to this work, and also fully illustrated in Plate 26.

As the opposition of these forces, however varied they may be in their directions and intensities, must ever represent a state of exact mechanical equilibrium, some apparently abnormal cases found on the ocean, and mostly south of the equator, must be accounted for; that they be not attributed to erroneous computation. For instance, Zone 24, serial numbers 10 to 21 et seq., and preceding zones, in reference to which foot-notes have usually been appended to the respective pages of the Tables. They are to be explained by the fact that the observations in those localities were not numerous enough to be taken as the basis of a reliable annual resultant, and, therefore, the monsoon influences were obtained by comparing the separate seasons—not with the meagre yearly resultant that they would have afforded—but with an annual resultant that was obtained by combining all the observations taken on that ocean, and within the limits of the zone.

PLATE 11.

MONSOON INFLUENCES IN THE UNITED STATES.

[See Explanation of Plate 10.1

The remarkable constancy of the winds between the Apallachian range and the Mississippi, and 34° and 42° N. lat., is especially to be noticed here. Hence the monsoon influences are extremely weak. The most powerful monsoon influences are seen in Texas, the region of the United States which is most like Eastern Asia in the course of its winds.

PLATE 12.

Monsoon Influences in Europe.

In winter a monsoon influence from the S. E. is seen in Europe; it is a reaction of the high pressure in the interior of the continent. In summer, on the contrary, except in a part of the Mediterranean region, the monsoon influences are from the west.

PLATE 13.

Annual Mean Direction of the Winds in the United States, showing that calculated when the Velocity is taken into account in comparison with that for Time only.

The first is expressed by broken arrows, the last by full arrows. It will be seen that the mean direction varies but little, if the velocity is taken into account, from that calculated from the time only. Generally in the first case the ratio of resultant is somewhat greater (the arrows longer). For a more extended view of this topic, compare with this map the diagrams found in Plate 25, and also the introduction to the Velocity Tables, in Series C.

PLATE 14.

Maps of Isobars or Lines of Equal Atmospheric Pressure at Sea-Level for the Year,
January and July.

These maps are inserted from the treatise of Buchan, "Mean Pressure and Prevailing Winds of the Globe," published in the Transactions of the Royal Society of Edinburgh, vol. xxv., which was the first attempt to do for the pressure of the air what Humboldt and Dove had done for temperature.

95 July, 1875.

A knowledge of the atmospheric pressure is of the greatest importance for the explanation of the courses of the winds. The explanation of these maps is found in the "Discussion and Analysis of Winds," where constant reference is made to it.

PLATES 15 TO 20 INCLUSIVE.

RELATIVE PREVALENCE OF WINDS, IN SUMMER AND WINTER, EXPRESSED IN PERCENTAGE.

PLATE 15. Arctic Regions.

Plate 16. Europe, south of latitude 60°.

PLATE 17. Asia and Africa, between 25° and 60° north latitude.

PLATE 18. Tropical Regions, north of the equator.

PLATE 19. Tropical Regions, south of the equator.

PLATE 20. South Temperate Regions, between latitude 25° and 60° south.

These six Plates represent the relative prevalence of winds from the different points of the compass in summer and winter, taken as the most marked seasons, and are adapted to the ready comparison and contrast of these seasons. The width of shading of the outer ring, reckoned from the circumference toward the centre, expresses in hundredths of an inch the percentage given in the Tables for the summer; in like manner, the inner belt of shading is used for the winter. The distance of these pairs of limiting circumferences from each other is 30 per cent.; when, therefore, the tabular percentage is in excess of this amount, the irregular contour line that marks the inner limit of the width passes into the next inner space.

Monsoon influences of marked character are vividly depicted in Plate 17 (Hakodade, Nangasaki and Pekin), Plate 18 (Celebes Sea and China Sea), and Plate 19 (Sween Island, Australia), the belts of shading far outstripping their limits, and even overlapping one another in the cases of Port Blair and Colombo, Ceylon. On the contrary, when the bands are symmetrical for the two seasons, these windroses show the absence of any noticeable monsoon influence, as on Plate 16, for Europe, in the cases of Dublin, Greenwich, St. Petersburg, Vladimir, Debrecziu and Gorki:

PLATE 21.

PERCENTAGE OF WINDS FOR THE FOUR SEASONS.

This Plate differs from the preceding only in containing windroses for spring and autumn, and illustrates the general similarity of the former to winter and of the latter to summer.

PLATE 22.

Relative Prevalence of Winds in the United States, in Summer and Winter, expressed in Percentage.

[Illustrated by Vertical Projection.]

This Plate, somewhat more compact in form, exhibits facts of the same nature as those contained in Plates 15 to 20, the percentage of winds at any place being represented in horizontal widths measured across the vertical bands. It enables one readily to find at what place wind from any particular direction is prevalent, by simply tracing down the column until great breadth is reached.

PLATE 23.

BAROMETRICAL WINDROSES.

This Plate was drawn by the author as an early attempt to illustrate the connection between the rise and fall of the barometer and corresponding changes in the direction of the wind. The width

of the shading at the several points of the compass shows the average rise or fall of the barometer per day while the wind is from those points, the + indicating a rise, and the — a fall; the two arrows starting from the centre are directed toward the points of maximum and minimum pressure; and a light line indicates the mean of the two. The arrow that springs from the circumference shows the mean annual direction of the wind. In order to compensate for the rare occurrence of winds from some directions, at several of the places, and make the shading more symmetrical, without affecting the principle of the illustration, the mean rise or fall for each point is combined, in several instances, with the two contiguous ones on either side, and the shading is proportioned to the new means thus found.

PLATE 24.

A METEOROLOGICAL CHART FOR OGDENSBURG, N. Y., 1838.

This plate is a suggestive presentation of meteorological facts. Drawn by the author, in January, 1839, it is believed to be the earliest American effort to connect and vividly illustrate the mutual relation between the results of a minute record of the winds, made by the aid of a self-registering vane, and so many as five of the points chiefly noted in the registers of meteorological observers, viz., amount of cloudiness, fall of rain and snow, and fluctuations in the barometer and thermometer. Deductions from this chart occupy pp. 220–227 of the Report of the Regents of the University of the State of New York, for the year 1838. Each of the circles gives a synchronous view, the shading corresponding in position with the wind then prevalent, and by its width indicating the amount of the contrasted element. From each month, arrows radiating from the centre denote the point of compass from which the wind came that was accompanied by a maximum or minimum of rainfall, thermometric fluctuation, etc.

PLATE 25.

VELOCITY CHART.

This illustrates minutely the general results of a series of observations, covering 700 years, and taken at 418 places on the American continent, from 1854 to 1857. The object was to determine what relation the average velocity of the winds, as a whole, and the varying and separate velocity of each particular wind, has to the results, as to direction and prevalence, that are obtained when the variation in velocity is disregarded. The solution of this question was viewed as vital to the correct study of the winds, and therefore of no small importance in the search for the laws of atmospheric circulation.

This plate shows that the resultants computed by assigning to each wind its own separate velocity differ from those in which the variation in velocity is disregarded, in being about 9° more northerly, and having a magnitude of 26 instead of 23 per cent.; and, further, that the velocity of all winds in the United States, north of latitude 33°, is a little more than seven miles per hour, resulting in a transfer of air in the mean direction of the main current at the rate of 2.0 or 1.7 miles per hour, according as velocity is counted or omitted.

The arrows represented as flying with the atmospheric current indicate the direction of the winds when only the time of their continuance is taken into account; the dotted lines show the result when the element of Velocity is also regarded. The height of the ordinates in the middle column is proportioned to the average velocity of the wind at each season of the year. In the right-hand vertical series of diagrams, the ordinates that terminate in a continuous line show the velocity of the wind in the mean direction, on the supposition that the entire current moves with the foregoing average velocity; while, in contrast, those ordinates that end in the broken (dotted) lines exhibit the result, as to velocity in the mean direction, when to each wind is assigned its own special velocity; when the latter class or ordinates is longer than the former, which is usually the case, the intervening space contains the sign +.

PLATE 26.

DEFLECTING FORCES.

The "S-shaped" curves _____ are divided into twelve parts to denote the path traversed by a particle of air, in each of the months of the year, when subjected to the winds that are found at Amherst, Massachusetts, Easton, Pennsylvania, New York City, Paris and Pekin, which are taken as representative places. In each case is seen the "parallelogram of forces," of which the diagonal represents the monthly resultant, one side one-twelfth of the yearly resultant, and another side the monsoon influence. Near each is gathered a parallel series of arrows to show the position of these monsoon influences relative to each other.

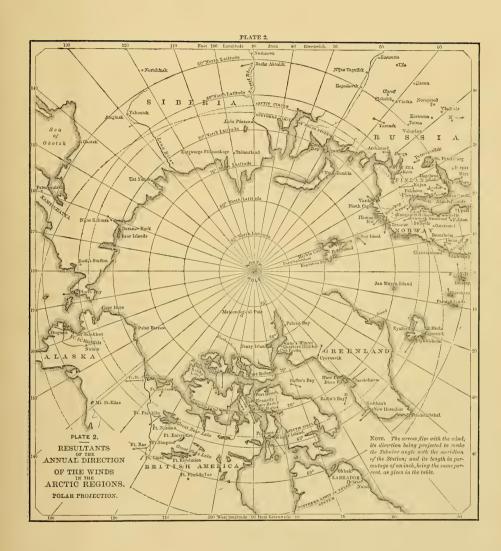

The law of the Monsoon Influences is seen in two facts: 1st. All these places, except Paris, are situated on the western shore of the adjacent oceans, and their monsoon influences are from the south-southeast in summer, and from the north-northwest in winter; but at Paris, not thus situated, their direction is reversed. And 2d. The monsoon influences at Pekin, which is emphatically in the monsoon region, and at New York, which is near the ocean, are greater than those at the other places which are not thus situated.

In the diagram at the right, in this Plate, representing an aggregate period of 560 years of observation, taken at more than 60 places in the State of New York, the approximate parallelism and equality of the arrows show the permanent character of the winds, and their divergence or insquality their annual mutations; yet the latter are rather apparent than real, since they are due chiefly to the introduction of new stations or discontinuance of old stations, so producing a slight modification of the result, and not indicating any really marked differences in the annual resultants. Two striking instances of diurnal variation in the direction of the wind are given on the lower part of the Plate for Hudson, Ohio, and St. Petersburg, which are easily explained by the proximity of each of these places to a considerable body of water situated north and northwest of them.

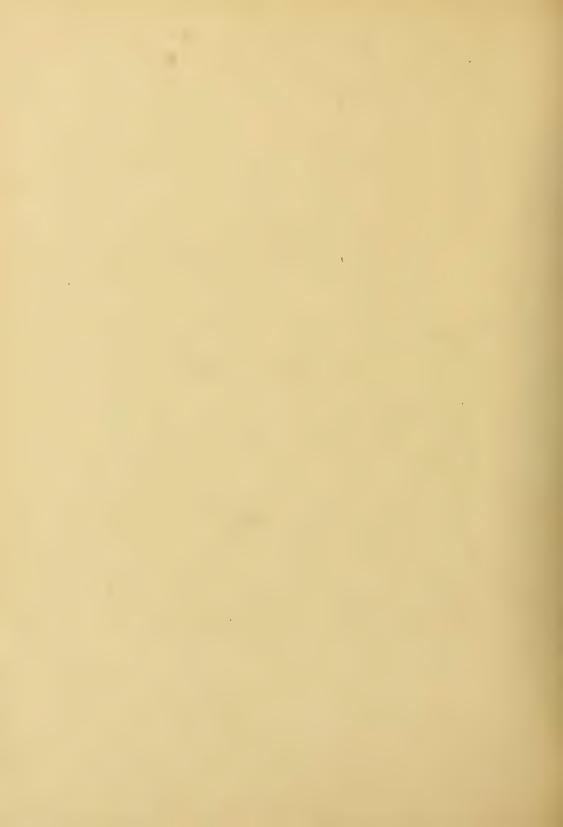

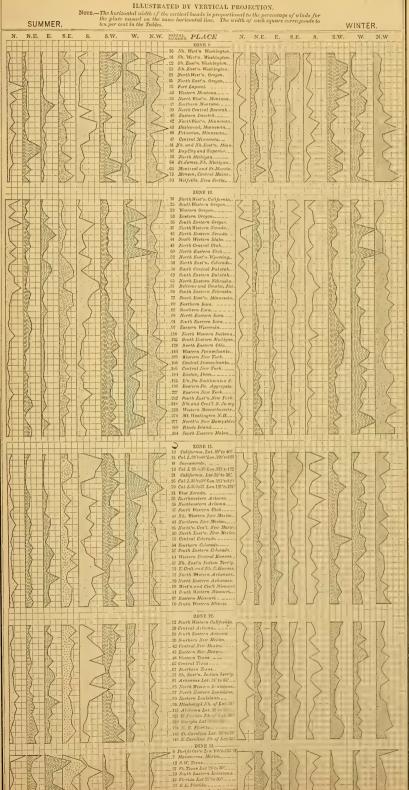

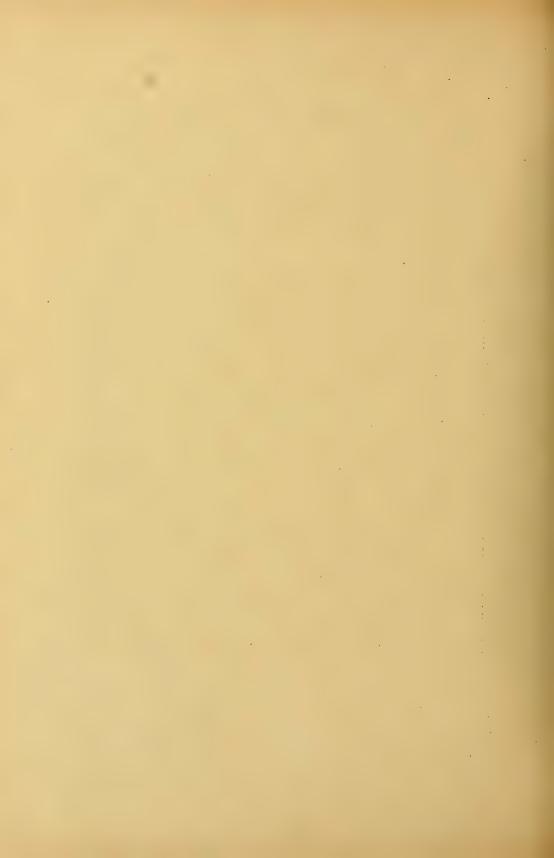

PLATE 22.

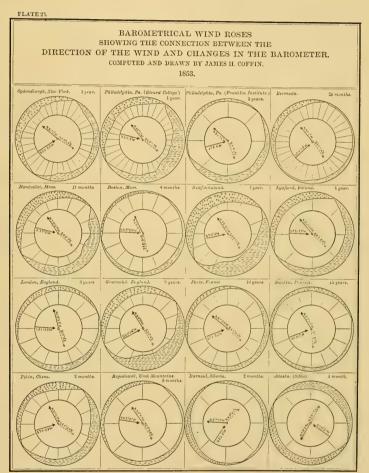

PERCENTAGE OF WINDS UNITED STATES

IN SUMMER AND WINTER

IN SUMMER AND WINTER

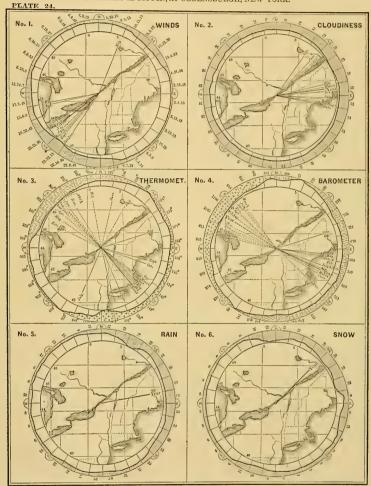

The width of the shading at the several points of compass shows the average RISE or FALL of the Barometer per day while the wind is from those points; the plus (+) denoting a rise, and the minus (-) a fall. The arrows that proceed from the centre, show the points of maximum and minimum pressure. The arrow pointing toward the centre shows the mean direction of the wind.

METEOROLOGICAL CHART.

SHOWING THE CONNECTION BETWEEN DIFFERENT METEOROLOGICAL PHENOMENA. COMPILED AND DRAWN FROM OBSERVATIONS MADE DURING THE YEAR 1838, BY JAMES H. COFFIN, AT OGDENSBURGH, NEW YORK.

The Maps of a region, about 300 miles around Ogleasburgh are surrounded by riags, in which the Meteorological Fiets are represented.

The width of the shaded portion at each point of Compass is proportional, in Figure 1, to the length of time that the Wind blee from that point during the year; in Figure 3 and 4, to the average Rive or Fill yer hour in the Thermoneter and B remoter, during such winds, the PLUS (4) showing a rive, and the MINISC - of sall in the instruments: and in Figures 2, 5 and 6, on the same prinriph, to the degree of Cloudiness, and to the average quantity of Rain or Stone falling per hour. The numbers in the margin require two decimal places in No. 2; three in No. 3; five in No. 4; and four in Nos. 5 and 6.

The CONTINUOUS lines diverging from Ogdensburg show the monthly maximum points of Wind, Temperature, Pressure and Cloudiness; and the DOTTED lines the minimum points. The heavy lines show the same for the year.
